ATA DE DEFESA - PÓS-GRADUAÇÃO

Programa de Pós-Graduação em:	Genética e Bioquímica				
Defesa de:	Doutorado Acadêmico - 07/2020 - PPGGB.				
Data:	Vinte e oito de janeiro de dois mil e vinte e um	Hora de início:	14:00h	Hora de encerramento:	17:56
Matrícula do Discente:	11623GBI006				
Nome do Discente:	Thaís Cunha de Sousa Cardoso				
Título do Trabalho:	New insights of miRNAs and metabolic pathways in tomato species and *Schistosoma haematobium*				
Área de concentração:	Bioquimica				
Linha de pesquisa:	Biologia Molecular				
Projeto de Pesquisa de vinculação:	Aplicação de métodos moleculares e computacionais para predição de genes codificadores de proteínas e pequenos RNAs				

Aos vinte e oito dias do mês de janeiro de dois mil e vinte e um, às 14:00 horas, reuniu-se via web conferência pela plataforma Google Meet, em conformidade com a Portaria nº 36, de 19 de março de 2020 da Coordenação de Aperfeiçoamento de Pessoal de Nível Superior – CAPES e Resolução de nº 06/2020 do Conselho de Pesquisa e Pós-graduação pela Universidade Federal de Uberlândia, a Banca Examinadora, designada pelo Colegiado do Programa de Pós-graduação em Genética e Bioquímica, assim composta: Prof. Dr. Antonio Chalfun Junior, Profª. Drª. Renata Guerra de Sá Cota, Prof. Dr. Aulus Estevão Anjos de Deus Barbosa, Profª. Drª. Enyara Rezende Morais e Prof. Dr. Matheus de Souza Gomes, orientador da candidata e demais convidados presentes conforme lista de presença. Iniciando os trabalhos o presidente da mesa, Prof. Dr. Matheus de Souza Gomes, apresentou a Comissão Examinadora e a candidata agradeceu a presença do público, e concedeu à discente a palavra para a exposição do seu trabalho. A duração da apresentação da discente e o tempo de arguição e resposta foram conforme as normas do Programa de Pós-graduação em Genética e Bioquímica. A seguir o presidente concedeu a palavra, pela ordem sucessivamente, aos examinadores, que passaram a arguir a candidata. Ultimada a arguição, que se desenvolveu dentro dos termos regimentais, a Banca, em sessão secreta, atribuiu os conceitos finais. Em face do resultado obtido, a Banca Examinadora considerou a candidata:

APROVADA

Esta defesa de Tese de Doutorado é parte dos requisitos necessários à obtenção do título de Doutor. O competente diploma será expedido após cumprimento dos demais requisitos, conforme as normas do Programa, a legislação pertinente e a regulamentação interna da UFU. Nada mais havendo a tratar foram

encerrados os trabalhos. Foi lavrada a presente ata que após lida e achada conforme foi assinada pela Banca Examinadora.

Documento assinado eletronicamente por **Matheus de Souza Gomes**, **Presidente**, em 28/01/2021, às 18:00, conforme horário oficial de Brasília, com fundamento no art. 6º, § 1º, do Decreto nº 8.539, de 8 de outubro de 2015.

Documento assinado eletronicamente por **Enyara Rezende Morais**, **Membro de Comissão**, em 28/01/2021, às 18:00, conforme horário oficial de Brasília, com fundamento no art. 6º, § 1º, do Decreto nº 8.539, de 8 de outubro de 2015.

Dedico esta tese aos meus pais, Pedro e Helânia, à minha irmã, Ana Cecília e ao meu namorado, Daniel, pelo incentivo constante e apoio incondicional.

AGRADECIMENTOS

A Deus, que me concedeu saúde e sabedoria para conduzir esta pesquisa e serenidade para enfrentar os desafios que, a cada passo, apostavam-se em meu percurso.

Aos meus pais, Pedro e Helânia e minha irmã, Ana Cecília, que sempre me apoiaram e me incentivaram em todos os meus projetos, fazendo-me acreditar na possibilidade da realização de meus sonhos.

Ao meu namorado, Daniel, pelo incentivo constante e compreensão em todos os momentos.

Aos demais familiares, pelas orações, carinho e preocupação.

Aos meus amigos, pelo companheirismo, sobretudo nos momentos de distração e desabafos.

Ao meu orientador, Prof. Dr. Matheus de Souza Gomes, pela oportunidade, amizade, ensinamentos, compreensão, dedicação e confiança.

À equipe do Laboratório de Bioinformática e Biologia Molecular (LBAM), pelas colaborações e auxílio. Em especial ao Carlos e Tamires, que participaram diretamente deste trabalho.

Ao CNPq, CAPES e FAPEMIG, que colaboraram com recursos financeiros e fomento de bolsas.

E por todos aqueles que participaram direta ou indiretamente na realização deste trabalho.

1 APRESENTAÇÃO

A família *Solanaceae* é uma das maiores famílias do reino vegetal, incluindo várias plantas de importância agronômica e médica, sobretudo o tomate, por seu alto consumo a nível mundial. Além de sua importância como alimento, o tomate possui características agronômicas interessantes, a saber, fruto carnoso e folhas compostas, que plantas modelo não possuem, ex. *Arabidopsis thaliana*. Nesse sentido, o tomate comum (*Solanum lycopersicum*) tem sido utilizado como modelo para espécies que também apresentam tais características.

Devido às características específicas e às condições de cultivo, as variedades de tomate são constantemente melhoradas. No entanto, essa cultura é suscetível a diversas pragas e patógenos. Para auxiliar no controle dessas doenças, a maioria dos produtores opta pelo uso de agentes químicos que, muitas vezes, são caros, às vezes ineficazes e têm efeitos deletérios ao meio ambiente. Uma alternativa para esses problemas é cruzar o tomate cultivado com espécies silvestres.

São várias as espécies conhecidas de tomate selvagem, constituídas por recursos genéticos pouco explorados e de grande importância para o melhoramento, pesquisa e desenvolvimento da cultura, como o *Solanum pennellii, Solanum galapagense, Solanum chilense, Solanum peruvianum* e *Solanum pimpinellifolium*. Algumas espécies de tomate selvagem têm sido amplamente utilizadas para a construção e mapeamento de populações devido a sua tolerância ao estresse ambiental. Nesse sentido, um melhor entendimento da base molecular do tomate é necessário para se atingir a eficiência e o sucesso na seleção de marcadores associados às características de interesse, como a tolerância biótica e abiótica.

Da mesma forma que é importante obter um maior conhecimento sobre as bases moleculares de muitas espécies de plantas, alguns animais, parasitas, bactérias e vírus também necessitam de estudos moleculares para auxiliarem no controle de doenças que acometem os serem humanos. Neste sentido, a esquistossomose humana é uma doença parasitária causada por helmintos do gênero *Schistosoma* que afeta milhões de pessoas em todo o mundo. Cinco espécies de *Schistosoma* são responsáveis pela maioria das infecções humanas:

Schistosoma mansoni, *Schistosoma japonicum*, *Schistosoma haematobium*, *Schistosoma mekongi* e *Schistosoma intercalatum*.

O *S. haematobium* afeta o sistema reprodutivo e urinário e tem sido considerado um grande problema de saúde pública na África. A disseminação da doença é dependente da interação entre o parasita e o hospedeiro intermediário. Esta interação é complexa e determinada por alguns genes envolvidos na infectividade do parasita e suscetibilidade do hospedeiro. Portanto, compreender os mecanismos de regulação gênica é extremamente importante para compreender as interações parasita-hospedeiro e quais genes podem contribuir para a infecção.

O progresso atual no sequenciamento do genoma de plantas e animais tem gerado informações úteis para auxiliar no estudo da diversidade genética de muitas espécies. Nos anos 2000 foram sequenciados os genomas de *S. galapagense, S. peruvianum*, *S. haematobium, S. lycopersicum*, *S. pennellii, S. pimpinellifolium* e *S. chilense*. A interpretação dos genomas do esquistossomo melhorou nosso entendimento da biologia molecular desses parasitas, permitindo a identificação e caracterização de genes ainda não descobertos.

A disponibilidade de um genoma de referência de tomate forneceu um arcabouço para a análise genômica da família *Solanaceae*, gerando uma fonte de informações importantes para seu melhoramento molecular. Além disso, o sequenciamento de genomas de espécies selvagens de tomate forneceu um recurso valioso para a compreensão de várias características proeminentes, como mudanças na resposta ao déficit hídrico, resistência biótica e abiótica e metabolismo. Entretanto, várias partes desses genomas precisam ser exaustivamente estudadas e anotadas, uma vez que o sequenciamento do genoma e o depósito das sequências em bancos de dados públicos são apenas os passos iniciais do estudo.

Estudos recentes têm mostrado a importância da regulação gênica envolvendo várias classes de pequenos RNAs, seu sistema de processamento e desempenho celular em diferentes organismos. Os principais representantes dessa classe de pequenos RNAs são os microRNAs (miRNAs), cujas formas de regulação podem envolver a inibição do processo de tradução, degradação de RNAm ou silenciamento de genes, seja por complementaridade de alvos ou por

sinalização de modificações no DNA em regiões específicas do genoma. Diferentes proteínas atuam para gerar miRNAs maduros específicos para a regulação pós-transcricional. Em plantas e animais estas vias de síntese dos miRNAs possuem algumas diferenças.

Estratégias computacionais têm sido usadas para identificar miRNAs e proteínas envolvidas em suas vias em vários organismos. Os métodos computacionais são amplamente utilizados na identificação de genes, uma vez que alguns transcritos são expressos apenas sob certas condições ou em células específicas. Assim, as técnicas computacionais auxiliam no processo de descoberta de novos miRNAs, utilizando todas as informações contidas no genoma e/ou no transcriptoma independentemente da amostragem. Além disso, tais métodos são úteis para a previsão de precursores de miRNA e seus alvos.

Diante da importância de tais RNAs não codificantes na regulação da expressão gênica, é importante estudarmos miRNAs maduros e precursores, bem como os genes envolvidos na via de miRNA nestas espécies de tomate cultivado e selvagens para auxiliar na elucidação de processos biológicos, bem como seus desempenhos no nível celular. Também em *S. haematobium,* o conhecimento destas pequenas moléculas e sua via de processamento pode ajudar a entender o ciclo de vida desse parasita, seu mecanismo de infectividade e na busca de novos métodos de controle da esquistossomose.

Além da via de produção dos miRNAs, outras vias de defesa são importantes em algumas plantas. Diferentes aleloquímicos presentes em espécies de *Solanum* têm sido associados à resistência a pragas, como metil-cetonas, sesquiterpenos e acilaçúcares. A seleção para altos teores destes aleloquímicos poderia, desta maneira, constituir-se uma técnica eficiente de seleção indireta para resistência a pragas. Esses fitoquímicos purificados podem agir contra as pragas reduzindo o desenvolvimento larval, prejudicando a alimentação e a ovoposição de muitas pragas do tomate.

Tendo em vista a grande importância do tomate e a alta taxa de aplicação de agrotóxicos na cultura, um maior conhecimento sobre as bases moleculares do tomate faz-se necessário na seleção de marcadores associados a características importantes em resposta ao estresse biótico e abiótico. Portanto, compreender os miRNAs, sua via de processamento e os genes relacionados com a produção de

metabólitos poderá auxiliar na compreensão do seu envolvimento na resistência a artrópodes, principalmente pela produção de acilaçúcar e a regulação pós transcricional mediada pelos miRNAs.

Tendo em vista essas questões, o Capítulo I apresentará a fundamentação teórica sobre os miRNAs, acilaçucares e suas vias, além da importância de estudar estas moléculas em *S. lycopersicum, S. pennellii, S. galapagense, S. chilense, S. peruvianum*, *S. pimpinellifolium e S. haematobium.* No Capítulo II serão expostos os artigos publicados e submetidos referente às pesquisas realizadas durante o doutorado.

2 CAPÍTULO I: Fundamentação teórica

2.1 Os microRNAs

Diversos estudos têm mostrado a importância da regulação gênica, envolvendo várias classes de pequenos RNAs, suas vias de processamento e sua atuação a nível celular em diferentes organismos (AXTELL, 2013; FOURACRE; POETHIG, 2016; KANG *et al*., 2014; MOAZED, 2009b; VIDIGAL; VENTURA, 2015; WEN *et al*., 2014). Essas classes de pequenos RNAs incluem os pequenos RNAs de interferência (siRNAs), pequenos RNAs de interferência com repetições associadas (rasiRNAs), pequenos RNAs de interferência que atuam em "trans" (tasiRNAs), pequenos RNAs de interferência anti senso naturais (natsiRNAs), RNAs que interagem com a proteína PIWI (piRNAs) e microRNAs (miRNAs), que diferem em processamento, tamanho e função celular (AXTELL, 2013; BARTEL, 2004; FOURACRE; POETHIG, 2016; KIM, 2008; WEN *et al*., 2014).

Os principais representantes das classes de pequenos RNAs são os miRNAs, se destacando pelas suas diversas funções na regulação da expressão de RNAs mensageiros (RNAm) a nível celular. Essa regulação pode ocorrer a partir da inibição do processo de tradução, por degradação do RNAm ou por silenciamento do gene, seja por complementaridade do alvo, ou sinalizando modificações no DNA em regiões específicas do genoma, influenciando o processo de expressão gênica em diferentes organismos (AGRAWAL *et al*., 2003; BARTEL, 2004; BENTWICH, 2005; DOENCH; PETERSEN; SHARP, 2003; GOMES *et al*., 2009; RAO *et al*., 2009). Os miRNAs são uma classe de pequenos RNAs endógenos, presentes em plantas e animais, que não codificam proteínas, com aproximadamente 21 nucleotídeos de comprimento quando maduro (BARTEL, 2004; CARTHEW; SONTHEIMER, 2009; WAHID *et al*., 2010). Os genes precursores destes miRNAs são encontrados em plantas, principalmente em regiões intergênicas no genoma (BARTEL, 2004; CHEN, 2008; DE SOUSA CARDOSO *et al*., 2015; LANG *et al*., 2011; ZHOU *et al*., 2011a).

Em sua via de processamento, atuam diferentes proteínas capazes de gerar um miRNA específico, para que ocorra uma fina e característica regulação

ao nível de genoma e/ou transcriptoma (AXTELL, 2013; DHIR; PROUDFOOT, 2013; KIM; HAN; SIOMI, 2009).

Em plantas, o processamento do miRNA ocorre primeiramente no núcleo a partir da transcrição realizada pela RNA polimerase II (Pol II), resultando em um longo miRNA primário (pri-miRNA). Até pouco tempo, era considerado que os pri-miRNAs não possuíam a capacidade de codificar nenhuma proteína. No entanto, Lauressergues e colaboradores (2015) apresentaram que alguns pri-miRNAs codificam peptídeos que aumentam a produção de seus miRNAs (LAURESSERGUES *et al*., 2015; WATERHOUSE; HELLENS, 2015).

No processo de geração dos miRNAs maduros em plantas, as enzimas RIBONUCLEASE III (RNase III), DICER-LIKE 1 (DCL1), associadas a outras enzimas, SERRATE (SE) e HYPONASTIC LEAVES 1 (HYL1), clivam o pri-miRNA, gerando o precursor de miRNA (pré-miRNA) (AXTELL; WESTHOLM; LAI, 2011; BUDAK; AKPINAR, 2015; JONES-RHOADES; BARTEL; BARTEL, 2006; KAPOOR *et al*., 2008; WAHID *et al*., 2010; WATERHOUSE; HELLENS, 2015). O pré-miRNA possui uma estrutura secundária característica, formando um grampo (*hairpin*) a partir de uma complementaridade imperfeita, contendo de 200-300 nucleotídeos de comprimento (KIDNER; MARTIENSSEN, 2005; WINTER *et al*., 2009). Mais uma vez as enzimas DCL1 e HYL1 atuam, clivando o pré-miRNA na extremidade que possui o hairpin, formando um miRNA/miRNA fita dupla, sendo, em seguida, metilado por uma metiltransferase HUA ENHANCER (HEN1), estabilizando a molécula e impedindo a sua uridilação e degradação posterior pelas exonucleases SDN (*small RNA degrading nuclease*) (BUDAK; AKPINAR, 2015; LI *et al*., 2005; YANG *et al*., 2006). O miRNA maduro então é exportado para o citoplasma pela HASTY (HST), homóloga da proteína Exportina-5 (XPO5), proteína presente dos animais (BARTEL, 2004; BRODERSEN; VOINNET, 2006; WAHID *et al*., 2010). O miRNA fita dupla metilado é, na sequência, carregado por um complexo de enzimas liderado pela ARGONAUTA (AGO), momento em que ocorre o desanelamento da fita dupla, sendo uma fita degradada e a outra direcionada, junto ao complexo RISC, ao reconhecimento específico do RNAm alvo, com a finalidade de regular a expressão gênica: por inibição da tradução ou degradação do RNAm (AXTELL, 2013; KAPOOR *et al*., 2008; PETERS; MEISTER, 2007; WINTER *et al*., 2009).

Em animais, a diferença da via de processamento dos miRNAs é que os pri-miRNA são clivados por um complexo que envolve a enzima RNAse III de cadeia dupla (DROSHA) e a proteína de ligação DGCR8 (DiGeorge Syndrome Critical Region 8 protein) (RUBY *et al*., 2007). A DROSHA contém dois domínios de RNAse III, cada qual cliva uma fita do RNA sintetizando o pré-miRNA com aproximadamente 70 pares de bases (pb). O pré-miRNA é transferido para o citoplasma por meio da proteína XPO5, onde, então, é clivado pela DCL1.

Em plantas e em animais há diversos miRNAs que possuem alvos importantes no organismo. Isso faz com que essas pequenas moléculas consigam fazer uma regulação fina e específica de diversos processos biológicos dentro das células. Algumas das funções importantes que os miRNAs apresentam no organismo de plantas e animais estão relacionados a: diferenciação e crescimento de células, apoptose, florescimento, fertilidade, defesa contra patógenos, coordenação da homeostase, regulação do desenvolvimento foliar e floral, transdução de sinais, acumulação de fatores de transcrição e respostas ao estresse (AXTELL, 2013; JONES-RHOADES; BARTEL; BARTEL, 2006; LI; MAO, 2007; MALLORY; VAUCHERET, 2006; MARTÍNEZ DE ALBA; ELVIRA-MATELOT; VAUCHERET, 2013; WAHID *et al*., 2010). Diante disso, o estudo do genoma e transcriptoma de plantas e animais tem se tornado uma ferramenta muito poderosa para auxiliar na elucidação de processos biológicos bem como suas atuações a nível celular (AMBROS *et al*., 2003; SRIVASTAVA *et al*., 2014; ZHANG *et al*., 2005; ZHOU *et al*., 2008).

A publicação dos genomas de *S. galapagense, S. peruvianum*, *S. haematobium, S. lycopersicum*, *S. pennellii, S. pimpinellifolium* e *S. chilense* representou um grande avanço no estudo da biologia destas importantes espécies (BOLGER *et al*., 2014; FERNANDEZ-POZO *et al*., 2015; RAZALI *et al*., 2018; SATO; TABATA, 2016; SATO; TABATA; HIRAKAWA, 2012; STAM *et al*., 2019; STRICKLER *et al*., 2015; YOUNG *et al*., 2012). No entanto, várias partes destes genomas necessitam ser profundamente estudadas e anotadas, uma vez que o sequenciamento do genoma e o depósito das sequências em bancos de dados públicos representam apenas os passos iniciais neste estudo.

Diversas estratégias computacionais e experimentais têm sido utilizadas para identificação de miRNAs e as proteínas de seu processamento em vários

organismos (HUANG *et al*., 2011; LI *et al*., 2010; ZHANG *et al*., 2005). Os métodos computacionais têm sido bastante utilizados na identificação de genes uma vez que alguns transcritos são expressos apenas em determinadas condições, em células específicas, ou são pouco expressos, sendo impossível sua identificação *in vitro*. Assim, as técnicas computacionais auxiliam no processo de descoberta de novos miRNAs, utilizando todas as informações contidas no genoma e/ou transcriptoma independentemente da amostragem. Além disso, esses métodos são úteis para a predição de precursores de miRNA e seus alvos. Contudo, muitos genes de miRNAs e seus alvos ainda não foram identificados em vários organismo, principalmente em plantas (LI *et al*., 2010; SRIVASTAVA *et al*., 2014; ZHANG *et al*., 2005).

2.2 *Schistosoma haematobium*

A esquistossomose humana é uma doença parasitária, crônica e debilitante causada por helmintos do gênero *Schistosoma,* que afeta atualmente cerca de 240 milhões de pessoas em todo o mundo, segundo a Organização Mundial da Saúde (MOHAMMED *et al*., 2015; WHO, 2020). Os países da África e da América do Sul estão entre os mais afetados. Além disso, 700 milhões de pessoas vivem em áreas de risco de contrair a doença (MCMANUS *et al*., 2018). Cinco espécies de *Schistosoma* são responsáveis pela maioria das infecções humanas: *S. mansoni*, *S. japonicum*, *S. haematobium*, *S. mekongi* e *S. intercalatum* (MOHAMMED *et al*., 2015).

O ciclo de vida do esquistossomo ocorre em dois hospedeiros: caramujos e mamíferos. O tipo de reprodução (assexuada ou sexual) acontece de acordo com o hospedeiro. A reprodução assexuada ocorre em caramujos de água doce, iniciando com o desenvolvimento de miracídios em esporocistos, os quais se multiplicam e se transformam em cercarias. Nos hospedeiros mamíferos, os parasitas crescem para amadurecer, acasalar e produzir ovos (MOUAHID *et al*., 2018; NELWAN, 2019; VIANA *et al*., 2018). Hospedeiros mamíferos liberam ovos de vermes no ambiente externo por meio de fezes ou urina. Em água doce, esses ovos formam miracídios, que eclodem e infectam os caramujos. Os miracídios desenvolvem nos caramujos que, por sua vez, podem eliminar centenas de

cercarias diariamente. As cercárias penetram na pele humana e perdem sua cauda bifurcada, formando esquistossômulos, os quais migram pelos tecidos do corpo através da circulação sanguínea e se transformam em esquistossomos e vermes adultos (GEYER *et al*., 2018; GURARIE *et al*., 2018; MOUAHID *et al*., 2018; NELWAN, 2019; SHUJA *et al*., 2018).

O *S. haematobium* afeta o sistema reprodutivo e urinário e tem sido considerado um grande problema de saúde pública principalmente na África (MOHAMMED *et al*., 2015; RISIKAT; AYOADE, 2012). A infecção por esse parasita pode resultar em deficiências nutricionais e retardo de crescimento, podendo também levar à diminuição da sistema cognitivo (STEPHENSON, 1993). A propagação desta doença ocorre por água doce e pela presença de caramujos hospedeiros. Atividades em contato com a água, como a agricultura, podem facilitar a infecção pelo parasita (RISIKAT; AYOADE, 2012). Em *S. mansoni* e seu hospedeiro intermediário *Biomphalaria glabrata*, a interação é complexa e determinada por alguns genes envolvidos na infectividade do parasita e suscetibilidade do hospedeiro (LEWIS, F. A., RICHARDS, C. S., KNIGHT, M., COOPER, L. A., CLARK, 1993; RICHARDS, 1970; RICHARDS; SHADE, 1987). Assim, também é sugerida uma interação hospedeiro-parasita complexa, envolvendo vários genes entre *S. haematobium* e seu caramujo hospedeiro intermediário, do gênero *Bulinus*. Portanto, compreender os mecanismos de regulação gênica é extremamente importante para compreender as interações parasita-hospedeiro e quais genes podem contribuir para a infecção.

A regulação da expressão gênica em eucariotos compreende processos envolvidos na repressão da tradução e/ou degradação de genes alvo (BARTEL, 2009). Pequenos RNAs, como miRNAs, e suas vias de silenciamento têm sido considerados importantes em diversos organismos por realizarem uma regulação específica da expressão gênica mantendo a integridade do genoma (BARTEL, 2009; MOAZED, 2009a). Os genes envolvidos na via de silenciamento gênico mediada por miRNAs foram descritos em vários organismos modelo, como *Drosophila melanogaster*, *Caenorhabditis elegans* e *Homo sapiens* (AMBROS, 2003; LEE *et al*., 2004; SIOMI; SIOMI, 2008). Além disso, membros da via biosintética de miRNAs, como AGO e DCL, assim como moléculas de miRNA,

foram relatadas em algumas espécies de *Schistosoma*, incluindo *S. mansoni* e *S. japonicum* (GOMES *et al*., 2009; YOUNG *et al*., 2012).

Young *et al*., publicaram em 2012 a sequência do genoma completo de *S. haematobium* (YOUNG *et al*., 2012). A interpretação dos genomas do esquistossomo melhorou nosso entendimento da biologia molecular desses parasitas, permitindo a identificação e caracterização de genes ainda não descobertos. Diante da importância amplamente aumentada de tais RNAs não codificantes na regulação da expressão gênica, é importante estudarmos miRNAs maduros e precursores, bem como os genes envolvidos na via de miRNA em *S. haematobium*. Isso pode ajudar a entender o ciclo de vida desse parasita, seu mecanismo de infectividade e a busca de novos métodos de controle da esquistossomose.

2.3 O tomate

O tomate é uma das hortaliças mais importantes do mundo devido à sua importância na economia, na geração de empregos e renda, e no grande volume de mão de obra e recursos produzidos em sua cadeia produtiva e industrial (KNAPP, 2002; SATO; TABATA, 2016). Atualmente, o Brasil está entre os 10 maiores produtores do mundo, produzindo mais de 4 milhões de toneladas de frutos em 2019 (FAO, 2019; IBGE, 2020).

O gênero *Solanum* é um dos maiores entre as angiospermas e contém aproximadamente 1.500 espécies (BAUCHET; CAUSSE, 2012). *S. lycopersicum*, o tomate cultivado, tem maior destaque por ser uma dos frutos mais consumidas e estudadas (BAICHOO; JAUFEERALLY-FAKIM, 2016; KARKUTE *et al*., 2018; KIM *et al*., 2011; PEREZ-FONS *et al*., 2014). Além de ser um alimento nutritivo, o tomate possui muitas características interessantes como fruto carnudo com folhas compostas, tricomas multicelulares e glandulares, entre várias outras características importantes que outras plantas modelo (como por exemplo, *A. thaliana*) não possuem. Essas características fazem do tomate uma planta modelo para espécies que apresentam essas características (BEDINGER *et al*., 2011; CAMPOS *et al*., 2010; GAPPER; MCQUINN; GIOVANNONI, 2013; GIOVANNONI, 2004; KOBAYASHI *et al*., 2014).

A origem do tomate ocorreu na região ocidental das Américas Central e do Sul, envolvendo as regiões andinas do Equador, Bolívia, Peru, Colômbia e Chile (BAUCHET; CAUSSE, 2012; CARVALHO, 2014). A principal forma de consumo do fruto é *in natura*, caracterizando o tomate de mesa, o qual se destaca pelo seu alto valor nutritivo, apresentando 93% a 95% de água, baixo valor calórico, além de conter proteínas, carboidratos, cálcio, magnésio, ferro, zinco, fibras, vitamina C, potássio, licopeno e outros compostos essenciais na alimentação (BAUCHET; CAUSSE, 2012; KIM *et al*., 2011; TACO, 2011). O tomate possui também um grande mercado para o consumo do fruto processado de forma industrial, sobretudo na produção de molhos, extratos e sucos (MONTEIRO *et al*., 2008).

Devido às características específicas, as variedades de tomate são constantemente melhoradas de acordo com a região, a forma de cultivo e a finalidade do fruto após a colheita (CARVALHO, 2014). Estes fatores são essenciais para que pesquisadores e produtores possam melhorar a qualidade e produtividade de cultivares de tomateiro (GERSZBERG; HNATUSZKO-KONKA, 2015). Embora o tomateiro tenha se adaptado a diferentes ambientes, grande parte das variedades necessita de um clima ameno, com temperaturas em torno de 21° a 24°C, e de uma área ensolarada, que não ultrapasse os 35ºC para se obter uma produção de melhor qualidade (CAMARGO, 2006; CARVALHO, 2014; NAIKA *et al*., 2006). Em geral, as plantas comerciais de tomate *S. lycopersicum* são suscetíveis ao ataque de pragas e mais de 200 doenças causadas por diferentes tipos de patógenos, incluindo vírus, bactérias, fungos e nematoides (BAI; LINDHOUT, 2007; HAAPALAINEN, 2014; LUKYANENKO, 1991; MCGOVERN, 2015; NOWICKI *et al*., 2012). Seu controle é feito principalmente pelo uso de inseticidas e acaricidas, que, além de altos custos, envolvem aplicação intensiva, o que impacta negativamente o meio ambiente pela poluição ambiental e desequilíbrio ecológico (eliminação de inimigos naturais), e ainda são prejudiciais à saúde humana (ERCOLANO *et al*., 2012).

Uma alternativa para obter variedades melhoradas de tomateiro, com características desejadas pelos produtores e consumidores, tais como o aumento do potencial produtivo, precocidade, homeostase genética, uniformidade, qualidade do fruto e resistência a patógenos, insetos e estresses abióticos, além de minimizar a utilização de produtos químicos, é o cruzamento do tomate

cultivado com espécies selvagens (ALSEEKH *et al*., 2013; BOLGER *et al*., 2014; KAMENETZKY *et al*., 2010; KIMURA; SINHA, 2008; M. A. STEVENS; RICK C. M., 1986). Existem várias espécies conhecidas de tomate selvagem, consistindo em recursos genéticos subexplorados e de grande importância para o melhoramento, pesquisa e desenvolvimento da cultura (AFLITOS *et al*., 2014; BOLGER *et al*., 2014; KAMENETZKY *et al*., 2010; KIMURA; SINHA, 2008; MCDANIEL *et al*., 2016; MITTOVA; VOLOKITA; GUY, 2015; NOSENKO *et al*., 2016a; PERALTA; KNAPP; SPOONER, 2005; SPOONER; PERALTA; KNAPP, 2005).

S. pennellii é uma espécie de tomate selvagem, endêmica das regiões andinas da América do Sul, onde evoluiu para prosperar em ambientes áridos. Essa espécie é relativamente distante da espécie domesticada de *S. lycopersicum*, estimada em 2,7 milhões de anos, e tem sido largamente utilizado para a construção e mapeamento de populações e linhagens devido à sua tolerância ao estresse e morfologia incomum (BOLGER *et al*., 2014; FERNANDEZ-POZO *et al*., 2015; KAMENETZKY *et al*., 2010; RICK; TANKSLEY, 1981). O genoma nuclear de *S. lycopersicum* e *S. pennellii* possuem 12 cromossomos com aproximadamente 842 Mb e 1 Gb de tamanho, respectivamente (FERNANDEZ-POZO *et al*., 2015).

Essa espécie de tomate selvagem possui características bem específicas, como o sistema de acasalamento, a diversidade fitoquímica e a resistência a diferentes ambientes. Mesmo com essas especificidades, é sexualmente compatível com *S. lycopersicum*, oferecendo um conjunto de genes úteis para lidar com os desafios de reprodução existentes e gerando híbridos altamente produtivos possuindo as características almejadas. Nos dias de hoje, os produtores optam pelo plantio dessas cultivares híbridas, devido ao grande potencial dessas plantas que chegam ao mercado, ampliando a possibilidade de serem cultivadas com maior segurança (ALSEEKH *et al*., 2013; BAUCHET; CAUSSE, 2012).

A maioria das espécies selvagens possuem frutos verdes, exceto: *S. pimpinellifolium, S. galapagense e S. cheesmaniae.* Essas espécies também são consideradas as parentes mais próximas do tomate cultivado (DARWIN; KNAPP; PERALTA, 2003; SATO; TABATA; HIRAKAWA, 2012). *S. pimpinellifolium* é nativo de áreas de baixa elevação nas encostas ocidentais dos Andes no Peru e

Equador (GRANDILLO *et al*., 2011). É a espécie selvagem mais próxima proposta em relação ao tomate cultivado, contendo em seu gonema 12 cromossomos e ~807 – 923 Mb de tamanho, além de ser a única espécie selvagem de frutos vermelhos. *S. pimpinellifolium* tem sido usado para introduzir características como resistência à doenças e à sólidos solúveis, melhoradas em tomate cultivado (FERNANDEZ-POZO *et al*., 2015; GRANDILLO *et al*., 2011).

S. galapagense é uma espécie perene endêmicas das Ilhas Galápagos e possui um fruto de cor laranja. Recentemente, *S. galapagense* foi reconhecida como uma espécie separada de *S. cheesmaniae*, sendo que anteriormente, era nomeada como *S. lycopersicon cheesmaniae L. Riley var. menor (Hook.f)* (DARWIN; KNAPP; PERALTA, 2003). *S. galapagense* possui um genoma com ~742 Mb de tamanho e têm sido utilizado em programas de melhoramento, principalmente para melhorar a tolerância ao sal e à sólidos solúveis (GRANDILLO *et al*., 2011). A cor laranja do fruto nesta espécie é devido a uma variante dominante do gene *B* que resulta em aumento de 5 a 10 vezes no β-caroteno em comparação com o fruto vermelho (RONEN *et al*., 1999). Essas espécie possui outras diferenças fenotípicas do tomate cultivado, incluindo cheiro, resposta a patógenos, tricomas e morfologia foliar (DARWIN, 2009).

S. peruvianum é uma espécie de tomate selvagem mais distante incluído na seção *Lycopersicon* e possui um genoma com 12 cromossomos e ~25 Mb de tamanho (FERNANDEZ-POZO *et al*., 2015; PERALTA, I. E., SPOONER, D. M., AND KNAPP, 2008). Vários acessos de *S. peruvianum* foram identificados como resistentes a pragas, doenças e estresses abióticos, tornando-os uma fonte de novos genes para reprodução. No entanto, seu uso tem sido limitado devido a barreiras de incompatibilidade e problemas de fertilidade de suas progênies (RICK, 1986).

S. chilense é nativo da América do Sul, variando do sul do Peru ao norte do Chile, e colonizou uma ampla variedade de habitats. As populações de *S. chilense* são encontradas em regiões costeiras, mesmo em ambientes ligeiramente alcalinos, até regiões montanhosas de grande altitude. Também ocorre em habitats extremamente secos na borda do deserto do Atacama, bem como perto de rios e riachos (PERALTA, I. E., SPOONER, D. M., AND KNAPP, 2008). Esta espécie tem sido utilizada em estudos sobre seca (XIA *et al*., 2010),

salinidade (MARTÍNEZ *et al*., 2012; ZHOU *et al*., 2011b), tolerância ao frio (NOSENKO *et al*., 2016b), resistência a patógenos e evolução do gene de resistência (STAM; SCHEIKL; TELLIER, 2017), bem como adaptação a ambientes extremos (BÖNDEL; NOSENKO; STEPHAN, 2018). *S. chilense* possui um genoma com 12 cromossomos e ~930 Mb de tamanho (FERNANDEZ-POZO *et al*., 2015), também vem sendo usada no melhoramento do tomate, alguns de seus genes foram introduzidos com sucesso para aumentar a resistência ao patógeno fúngico *Verticilium dahliae* (TABAEIZADEH *et al*., 1999) e ao vírus Y do mosaico do tomate (VERLAAN *et al*., 2013).

Nesse sentido, um maior conhecimento sobre as bases moleculares dessas espécies de tomate é necessário, para obter eficiência e sucesso na seleção de marcadores associados a características de interesse (GERSZBERG; HNATUSZKO-KONKA, 2015).

2.4 Os acilaçucares

Muitas espécies selvagens de tomate possuem diversos aleloquímicos que têm sido associados com a resistência a diversos artrópodes e pragas, no entanto estas espécies não possuem valor comercial imediato (SILVA, 2009; WILLIAMS *et al*., 1980). *S pennellii*, relativamente distante da espécie domesticada de *S. lycopersicum*, e tem sido largamente utilizado para a construção de populações e linhagens devido a sua tolerância ao estresse, resistência a pragas e morfologia incomum (BOLGER *et al*., 2014; FERNANDEZ-POZO *et al*., 2015). Acessos de *S. pennellii,* entre os quais o denominado LA-716, apresentam alto nível de resistência à mosca branca, bem como a afídeos, ácaros rajados, lepidópteros, inclusive à traça-do-tomateiro, pragas relevantes do tomateiro e de importância mundial (GENTILE; WEBB; STONER, 1968, 1969; GOFFREDA *et al*., 1989).

Diferentes aleloquímicos presentes em espécies de *Solanum* têm sido associados à resistência a pragas: metil-cetonas como a 2-tridecanona em *S. habrochaites* var. *glabratum* (GONÇALVES *et al*., 1998; MALUF; BARBOSA; SANTA-CECÍLIA, 1997), sesquiterpenos em *S. habrochaites* var. *hirsutum* (EIGENBRODE *et al*., 1994) e acilaçúcares em *S. pennellii* (FREITAS *et al*., 2002; GOFFREDA *et al*., 1989). A seleção para altos teores destes aleloquímicos

poderia desta maneira, constituir-se uma técnica eficiente de seleção indireta para resistência a pragas, como a traça-do-tomateiro (GONÇALVES NETO *et al*., 2010; RESENDE *et al*., 2006), a mosca branca (FREITAS *et al*., 2002) e ácaros *Tetranychus* spp. (MALUF; CAMPOS; DAS GRAÇAS CARDOSO, 2001).

Esta resistência de amplo espectro é atribuída à presença de tricomas glandulares que ocupam a superfície da planta, principalmente tricomas do tipo IV, bem como aos aleloquímicos por eles secretados (GENTILE; WEBB; STONER, 1968; GOFFREDA *et al*., 1989). Os acilaçúcares são ésteres de ácidos graxos com 4 a 12 átomos de carbono, contendo glicose ou sacarose, constituem aproximadamente 90% do total secretado pelo tricoma tipo IV, e podem representar um importante papel na resistência a pragas do tomateiro. Esses fitoquímicos purificados podem agir contra as pragas reduzindo o desenvolvimento larval, prejudicando a alimentação e a ovoposição de muitas pragas do tomate (HAWTHORNE *et al*., 1992; JUVIK *et al*., 1982).

Acilaçúcares encontrados na família das *Solanaceae* possuem um conjunto característico de moléculas entre as espécies, os quais podem deferir de acordo com a porção de açúcar, como glicose ou sacarose, a porção de ácidos graxos e a disposição da acilação (SHAPIRO; STEFFENS; MUTSCHLER, 1994). A variedade de estruturas das moléculas de acilaçúcares está relacionada com uma diversidade de vias biossintéticas (GOFFREDA; STEFFENS; MUTSCHLER, 1990; SHAPIRO; STEFFENS; MUTSCHLER, 1994).

Alguns trabalhos mostram a contribuição de algumas proteínas no metabolismo de acilaçucares em plantas, como as enzimas acetyl-CoA synthase (KANDRA; SEVERSON; WAGNER, 1990), aldo keto reductase (AKR), acetolactate/acetohydroxyacid synthase (ALS/AHAS) (KROUMOVA; WAGNER, 2003; NING *et al*., 2015; SLOCOMBE *et al*., 2008; WALTERS; STEFFENS, 1990), acylsugar acyltransferase 2/4/3 (AT2/AT4/AT3) (KIM *et al*., 2012; LECKIE; HALITSCHKE, 2014; NING *et al*., 2015; SCHILMILLER; CHARBONNEAU; LAST, 2012), branched-chain aminotransferase 2/5 (BCAT) (NING *et al*., 2015), branched-chain keto acid dehydrogenase E1a/E1b/E2 (BCKD) (NING *et al*., 2015; SLOCOMBE *et al*., 2008; WALTERS; STEFFENS, 1990), dihydroxyacid dehydratase (DHAD) (LECKIE; HALITSCHKE, 2014; NING *et al*., 2015; WALTERS; STEFFENS, 1990), dihydrolipoyl dehydrogenase (IPD) (KANDRA; SEVERSON; WAGNER, 1990), isopropylmalate dehydratase/isopropylmalate

isomerase (IPDS/IPMI) (KANDRA; SEVERSON; WAGNER, 1990; KROUMOVA; WAGNER, 2003; SLOCOMBE *et al*., 2008), isopropylmalate dehydrogenase (IPMD) (KANDRA; SEVERSON; WAGNER, 1990; NING *et al*., 2015; SLOCOMBE *et al*., 2008; WALTERS; STEFFENS, 1990), 2-isopropylmalate synthase A/B (IPMSA/IPMSB) (HOEVEN *et al*., 2000; KANDRA; SEVERSON; WAGNER, 1990; LECKIE; HALITSCHKE, 2014; NING *et al*., 2015; SLOCOMBE *et al*., 2008), isovaleryl-CoA dehydrogenase 1 mitocondrial/methylacyl-CoA dehydrogenase, ketol acid/acetohydroxy-acid reductoisomerase I (KARI) (NING *et al*., 2015; WALTERS; STEFFENS, 1990), ketoacyl-ACP synthase I, II, III e mitocondrial (KAS) (SLOCOMBE *et al*., 2008), 3-ketoacyl-CoA reductase 2 (KCR2) (MCDOWELL *et al*., 2011), 3-ketoacyl-CoA synthase 3/19 (KCS3/KCS19) (LECKIE; HALITSCHKE, 2014; MCDOWELL *et al*., 2011) e threonine deaminase/dehydratase (TD) (NING *et al*., 2015; SLOCOMBE *et al*., 2008; WALTERS; STEFFENS, 1990).

Dentre as principais proteínas envolvidas na via de acilaçucar, o complexo multienzimático BCKD é composto por três subunidades de enzimas, 2-oxo acid dehydrogenase (E1), dihydrolipoyl acyltransferase (E2) e dihydrolipoamide dehydrogenase (E3), o qual desempenha um papel fundamental na regulação redox. E2, o componente central do complexo, catalisa a transferência do grupo acil do CoA a partir de E1 a E3 através de acetilação redutora de um grupo lipoil, covalentemente ligado a um resíduo de lisina (CDD, 2016). BCKD catalisa a conversão de cetoácidos de cadeia ramificada em acil-CoAs de cadeia ramificada com a perda de um carbono, num processo de descarboxilação (SLOCOMBE *et al*., 2008). Em plantas, BCKD está envolvido no primeiro passo do catabolismo de aminoácidos de cadeia ramificada (BCAA), além de também atuar de forma importante na via de síntese de ácidos graxos de cadeia ramificada (BCFA) (MOONEY; MIERNYK; RANDALL, 2002; SLOCOMBE *et al*., 2008; TAYLOR *et al*., 2004). A enzima ACYLSUGAR ACYLTRANSFERASE2 (ASAT2) catalisa a transferência de um grupo acetil via acetil-CoA para um receptor tri-acilsucrose para formar as tetra-acilsucroses acetiladas produzidas por tricomas de tomate cultivados. No tomate cultivado, a ACYLSUGAR ACYLTRANSFERASE3 (ASAT3), catalisa a acilação R3′ no anel furanose de cinco membros das di-acilsucroses nas células da ponta dos tricomas produtores de acilçucar (SCHILMILLER *et al*., 2015; SCHILMILLER; CHARBONNEAU; LAST, 2012).

A enzima IPMS é responsável por catalisar a condensação do tipo aldol de acetil-CoA-redutase e 2-oxoisovalerato, obtendo 2-isopropilmalato e CoA, sendo esse o primeiro passo envolvido na biossíntese de leucina (CDD, 2016; HOEVEN *et al*., 2000). Ning *et al*. (2015) observou que *S. lycopersicum* expressa um gene IPMS (Solyc08g014230) no cromossomo 8 de células apicais dos tricomas do tipo I/IV, o qual codifica uma proteína final funcional com menos 160 aminoácidos (a.a.) na região C-terminal quando comparada com a IPMS do cromossomo 6 (NING *et al*., 2015). Mesmo a proteína sendo ativa *in vitro*, ela é insensível a inibição alostérica mediada pela ligação à leucina no domínio regulador descrita em *Arabidopsis* (KRAKER; GERSHENZON, 2011) e microorganismos (CARVALHO; ARGYROU; BLANCHARD, 2005; KOON; SQUIRE; BAKER, 2004; NING *et al*., 2015). Por outro lado, um gene IPMS (Sopen08g005140), localizado no cromossomo 8 de *S. pennellii* codifica uma proteína IPMS truncada não-funcional com uma deleção maior na região C-terminal (51 a.a.). Essa deleção encontrada em *S. pennellii* faz com que não haja a regulação alostérica pela ligação de leucina, acumulando então grandes quantidades de ácido metilpropanóico para a síntese de acilaçucar (NING *et al*., 2015). Dessa forma, esses resultados auxiliam uma maior compreensão dos mecanismos naturais de defesa nas diferentes espécies de *Solanaceas* para avanços no melhoramento tradicional e em manipulações genéticas de espécies comercialmente importantes.

Tendo em vista a grande importância do tomate e a alta taxa de aplicação de agrotóxicos na cultura, um maior conhecimento sobre as bases moleculares do tomate faz-se necessário na seleção de marcadores associados a características importantes em resposta ao estresse biótico e abiótico. A publicação dos genomas de várias espécies de tomate representou um grande avanço no estudo da biologia destas espécies, possibilitando um aprofundamento nos estudos, na anotação e identificação de diversos genes. Portanto, compreender os genes relacionados com a produção de metabólitos nos tricomas de *S. galapagense, S. peruvianum*, *S. haematobium, S. lycopersicum*, *S. pennellii, S. pimpinellifolium* e *S. chilense* poderá auxiliar na compreensão do seu envolvimento na resistência a artrópodes, principalmente pela produção de acilaçúcar.

3 CAPÍTULO II – Article: New insights into tomato microRNAs from Scientific Reports Journal

Algumas análises presentes no artigo *New insights into tomato microRNAs* a ser apresentado foram realizadas e defendidas no mestrado. No doutorado foram realizadas novas análises referentes a este trabalho para publicação.

Foram realizadas no mestrado:

- Predição dos genes e proteínas envolvidos na biogênese de pequenos RNAs, incluindo miRNAs em *S. lycopersicum* e *S. pennellii*;
- Predição de miRNAs maduros e precursores;
- Análise de domínios conservados, sítios ativos, filogenia e alinhamento de proteínas da via e precursores de miRNA em *S. lycopersicum* e *S. pennellii;*
- Predição dos genes alvos dos miRNAs identificados em *S. lycopersicum* e *S. pennellii.*

No doutorado:

- Expressão de miRNAs por PCR em tempo real:
    - Coleta das folhas, frutos e flores de *Solanum lycopersicum* e *Solanum pennellii;*
    - Extração e quantificação do RNA dos materiais vegetais;
    - Tratamento do RNA com DNAse;
    - Síntese do cDNA e expressão relativa dos miRNAs.
- Expressão de genes da via de miRNA em 18 bibliotecas de RNA-seq de tomate;
- Análise de miRNAs em 95 bibliotecas de smallRNAseq de *S. lycopersicum*;
- Análise estatística comparativa entre as variáveis estruturais e termodinâmicas de espécies e/ou famílias de miRNAs.

New insights into tomato microRNAs

ABSTRACT

Cultivated tomato, *Solanum lycopersicum*, is one of the most common fruits in the global food industry and together with the wild tomato *Solanum pennellii*, are both species widely used in developing better cultivars. microRNAs act on mRNA regulation, inhibiting their translation and/or promoting its degradation. Important proteins involved in these processes are ARGONAUTA and DICER. This study aimed to identify and characterize genes involved in miRNA processing pathways, miRNAs molecules and target-genes in the genome of both species using in silico analysis. We also validated the genes and miRNAs expression in different NGS libraries, in addition to validating some miRNAs using quantitative RT-PCR. We

identified 70 putative proteins in *S. lycopersicum* and 108 in *S. pennellii* involved in small RNAs processing. Of these, 28 and 32 participate in miRNA processing pathways, respectively. We identified 343 mature miRNAs, 226 pre-miRNAs in 87 families, including 192 miRNAs not previously identified, belonging to 38 new families in *S. lycopersicum*. In *S. pennellii*, we found 388 mature miRNAs, 234 pre-miRNAs contained in 85 families. All miRNAs found in *S. pennellii* were unpublished, being first identified in our study. Furthermore, we identified 2471 and 3462 miRNA different target in *S. lycopersicum* and *S. pennellii*, respectively.

3.1 INTRODUCTION

The *Solanaceae* family is one of the largest families in the plant kingdom, including several plants of agronomic and medical importance. It is composed of about 100 genera and more than 3000 species that grow in all habitats, ranging from rainforests to deserts. The tomato is one of the most important fruit crop in the global food industry[1–5]. The genus *Solanum* is one of largest genera among the *Angiosperms*, containing approximately 1500 species[6]. *Solanum lycopersicum,* the cultivated tomato is one of the most consumed fruits worldwide[7,8]. Besides its importance as food, the tomato has important agronomic characteristics, including fleshy fruits and multicellular and glandular trichomes, which model plants like *Arabidopsis thaliana* do not have. Thus, the common tomato has beend used as a model for species that also have these characteristics[9–13].

Due to the specific characteristics and growing conditions, tomato varieties are constantly improved[14]. However, this crop is susceptible to insect attacks and more than 200 diseases caused by various types of pathogens, including viruses, bacteria, fungi and nematodes[15]. To aid in the control of these diseases, most producers opt for the use of chemical agents, which are often costly, at times ineffective, and have deleterious effects on the environment[16]. An alternative to these problems is to cross the cultivated tomato with wild species[12,17–20]. There are several known species of wild tomato, consisting of underexploited genetic resources and of great importance for the improvement, research and development of culture[12,18,20–26]. *Solanum pennellii* is a species of wild tomato that has been widely used for the construction and mapping of populations due to its

tolerance to environmental stress[18,20,27,28]. In this sense, a better understanding of the molecular basis of the tomato is required to achieve efficiency and success in the selection of markers associated with characteristics of interest[4].

The current progress in sequencing the tomato genome has generated useful information to assist in the study of their genetic diversity[12,23]. The sequencing of the genome of *S. lycopersicum* was completed in 2012[29]. Furthermore, the availability of a reference genome provided a framework for the genomic analysis of *Solanaceae* family, generating a source of important information for their molecular breeding[5,13,30]. In addition to *S. lycopersicum*, the *S. pennellii* genome was also sequenced, which provided a valuable resource for the understanding of several prominent features, such as changes in response to water deficit, biotic and abiotic resistance, and metabolism[20,28]. However, various parts of these genomes need to be thoroughly studied and annotated since the sequencing of the genome and the deposit of the sequences in public databases are only the initial steps for a thorough understanding.

Although much is known about tomato biology, relatively little is known about the regulation of gene expression involved in plant development. Recent studies have shown the importance of gene regulation, involving several classes of small RNAs, their processing system and cellular performance in different organisms[31–36]. The main representatives of this class of small RNAs are the microRNAs (miRNAs), whose way of regulation may involve inhibition of the translation process, degradation of mRNA or gene silencing, either by target complementarity or by signaling DNA modifications in specific regions of genome[37–42]. miRNAs are endogenous small RNAs with approximately 21 nucleotides in length in mature form[37,43,44].

Different proteins act to generate a specific mature miRNA for post-transcriptional regulation[32,45,46]. In plants, miRNA processing first occurs in nucleus from the transcription resulting in a long primary miRNA (pri-miRNA) which after cleaved generate the miRNA precursor (pre-miRNA)[43,47–54]. The pre-miRNA has a characteristic secondary structure, forming a hairpin from an imperfect complementarity, containing from 200-300 nucleotides in length[55,56]. The pre-miRNA is also cleaved at the end of the hairpin, forming a duplex of mature miRNAs (miRNA/miRNA double strand). The mature miRNA is exported to the

cytoplasm and then loaded in a RISC complex, to specific recognition of the target mRNA to regulate gene expression either by translation inhibition or mRNA degradation[32,48,55,57–59].

Important biological functions are mediated by miRNAs, which include the adaptation of plants to stress, regulation of leaf and floral development, defense, cell proliferation, apoptosis and signal transduction[32,43,47,60–62]. Due to important and complex regulation mediated by the miRNAs, the expression detection and quantification of these molecules in specific tissues is essential for a better understanding of their action. Although miRNAs have a high degree of transcription, their expression levels fluctuate widely between cells and in among tissues. A sensitive and rapid method for the detection and quantification of miRNAs expression is the quantitative real-time PCR (qRT-PCR)[63–65]. In addition, several computational strategies have been used to identify miRNAs and proteins of their pathway in various organisms[66–68]. Computational methods are widely used in the identification of genes since some transcripts are expressed only under certain conditions or in specific cells. Thus, computational techniques aid in the discovery process of new miRNAs, using all the information contained in the genome and/or the transcriptome independently of the sampling. Furthermore, such methods are useful for prediction of miRNA precursors and their targets.

Previous studies have identified miRNAs and proteins involved in miRNA biogenesis in *S. lycopersicum*[69–7273–87]. Many of these studies have shown important roles of tomato miRNAs such as those seen in fruit ripening[78], response to long-term RPM-treatment[88], response to curl *New Delhi virus* (ToLCNDV)[76], responses associated to *Botrytis cinerea* infection[83], male-sterility[85], salt-induced stress response[79], biotic[80], drought[84], and high-temperature stress response[87]. However, many of these genes, miRNAs and their respective targets have not yet been identified and characterized systematically in tomato species, especially in *S. pennellii*. Thus, the study of miRNAs in the plant genome and transcriptome has become a very powerful tool to assist in elucidation of biological processes as well as their performances at the cellular level[67,89–91].

The aims of this study were to identify and characterize by in silico analysis the genes involved in miRNA processing, the miRNA precursors, the miRNA targets as well as to validate such miRNAs in different tissues of *S. lycopersicum*

and *S. pennellii*, using genomic and transcriptomic sequences obtained from public databases and RT-PCR. This study allows for a better understanding of miRNAs, their processing pathways and their role in regulating the gene expression of these important species, as well as providing targets for future investigations.

3.2 RESULTS

3.2.1 The small RNAs processing pathway in *S. lycopersicum* and *S. pennellii*: analysis of conserved protein domains, active sites and phylogenetic trees

To understand the potential roles of small RNAs in the regulation of gene expression in the tomato, we sought to initially identify all possible components of small RNAs of the processing machinery in *S. lycopersicum* and *S. pennellii* genomes. Using local alignment, as well as the presence and arrangement of conserved domains, 70 putative proteins were identified in *S. lycopersicum* and 108 in *S. pennellii* involved in the biogenesis of small RNAs (siRNAs, tasiRNAs and miRNAs) (data not shown). Among these proteins, AGO and DCL family, are considered key proteins in processing machinery of small RNAs in plants[47,92]. We identified 15 and 16 proteins which belong to the ARGONAUTE family in *S. lycopersicum* and *S. pennellii* respectively (SlyAGO1.1, SlyAGO1.2, SlyAGO2.1, SlyAGO2.2, SlyAGO2.3, SlyAGO4.1, SlyAGO4.2, SlyAGO4.3, SlyAGO4.4, SlyAGO4.5, SlyAGO5, SlyAGO6, SlyAGO7, SlyAGO10.1, SlyAGO10.2, SpeAGO1.1, SpeAGO1.2, SpeAGO2.1, SpeAGO2.2, SpeAGO2.3, SpeAGO4.1, SpeAGO4.2, SpeAGO4.3, SpeAGO4.4, SpeAGO4.5, SpeAGO4.6, SpeAGO4.7, SpeAGO5, SpeAGO6, SpeAGO7, SpeAGO10). 8 and 11 DICER family proteins were found in *S. lycopersicum* and *S. pennellii* respectively (SlyDCL1, SlyDCL2.1, SlyDCL2.2, SlyDCL2.3, SlyDCL2.4, SlyDCL3.1, SlyDCL3.2, SlyDCL4, SpeDCL1, SpeDCL2.1, SpeDCL2.2, SpeDCL2.3, SpeDCL2.4, SpeDCL2.5, SpeDCL2.6, SpeDCL3, SpeDCL4.1, SpeDCL4.2, SpeDCL4.3).

Among the proteins involved in small RNAs processing, 28 (*S. lycopersicum*) and 32 (*S. pennellii*) putative proteins were identified by

participating in the miRNAs pathway (Supplementary Table S1 and Supplementary Table S2).

3.2.2 ARGONAUTE and DICER proteins in *S. lycopersicum* and *S. pennellii*

3.2.2.1 Analysis of conserved domains, active sites, phylogeny and pathway proteins and pre-miRNA alignment in *S. lycopersicum* and *S. pennellii*

We found 15 AGO proteins in the genome of *S. lycopersicum* and 16 in *S. pennellii*. The SlyAGO1.1/1.2 and SpeAGO1.1/1.2 proteins displayed the Gly-rich_Ago1, ArgoN, ArgoL1, PAZ, ArgoL2, ArgoMid and Piwi domains. Similar results were observed for SlyAGO10.1/10.2 and SpeAGO10 which displayed the domains ArgoN, ArgoL1, PAZ, ArgoL2, ArgoMid and Piwi (Supplementary Figure S1 and Supplementary Table S3).

The Piwi conserved domains, one of the main domains present in AGO proteins, was identified in the SlyAGO1.1, SlyAGO1.2, SpeAGO1.1, SpeAGO1.2, SlyAGO10.1, SlyAGO10.2 and SpeAGO10 proteins. These domains showed active sites regions containing an important catalytic triad DDH (aspartate/aspartate/histidine). The DDH catalytic triad of these proteins was found in Asp764-Asp850-His990, Asp690-Asp776-His916, Asp763-Asp849-His989, Asp862-Asp948-His1088, Asp704-Asp790-His930, Asp658-Asp744-His884, Asp704-Asp790-His930 positions, respectively (Figure 1a).

In *S. lycopersicum* and *S. pennellii,* we identified 8 and 11 putative proteins, respectively, belonging to the DCL protein family. We found DCL1 (DCL proteins are involved in the miRNAs processing) in *S. lycopersicum* and *S. pennellii*. Both proteins displayed the conserved domains ResIII (also known as DEAD-like), Helicase C, Dicer Dimer (also known as DUF283), PAZ, Ribonuclease IIIa (RNase IIIa), Ribonuclease IIIb (RNase IIIb), dsrm and DND1 DSRM (Supplementary Figure S1 and Supplementary Table S4).

We found two RNAse III domains in SlyDCL1 and SpeDCL1 proteins. The two domains (RNase IIIa and RNase IIIb) had the same catalytic residues in the two tomato species studied: glutamate (E), aspartate (D), aspartate (D), glutamate (E), representing the EDDE active site. These residues were located in RNase IIIa

domains at Glu1591-Asp1595-Asp1687-Glu1690 and Glu1617-Asp1621-Asp1713-Glu1716 positions and the RNase IIIb domains at Glu1390-Asp1394-Asp1465-Glu1468 and Glu1390-Asp1394-Asp1521-Glu1524 positions of the SlyDCL1 and SpeDCL1 proteins, respectively (Figure 1b).

To understand the diversification of AGO proteins in *S. lycopersicum* and *S. pennellii*, a phylogenetic analysis was performed using their amino acid sequences (Figure 2). The phylogeny of the Sly/SpeAGO1 and Sly/SpeAGO10 proteins showed that they were distributed in the phylogenetic tree closest to their respective orthologous proteins from the plant species *S. tuberosum* and *Nicotiniana sylvestris.* The phylogenetic tree was divided into seven distinct clades of paralogous (AGO1, AGO2, AGO4, AGO5, AGO6, AGO7 and AGO10). In addition, to determine the evolutionary relationship among the putative DCL proteins of *S. lycopersicum*, *S. pennellii* and their orthologous species, a phylogenetic analysis was also conducted (Figure 3). The proteins were grouped through global alignment in four distinct clades (DCL1, DCL2, DCL3 and DCL4).

3.2.3 Mature miRNAs and their precursors in *S. lycopersicum* and *S. pennellii*

To show that the miRNA processing machinery is well conserved in *S. lycopersicum* and *S. pennellii*, we sought to identify both mature and precursor sequences of miRNAs, in addition to predicting and defining the nature of their putative target genes using available public databases (Phytozome v12.1 and PlaBi). By applying an optimized and specific algorithm (see material and methods), we identified 343 sequences of mature miRNAs with 285 different sequences and 226 precursor miRNAs, distributed in 87 distinct miRNA families in *S. lycopersicum* genome (Supplementary Table S5). In *S. pennellii*, 388 sequences of mature miRNAs with 307 different sequences and 234 precursor miRNAs contained in 85 different miRNA families were identified (Supplementary Table S6).

Regarding the miRNA precursor genes localization and distribution in *S. lycopersicum* and *S. pennellii* genomes, 196 (86.73%) and 195 (81.59%) were found in intergenic regions and 30 (13.27%) and 44 (18.41%) within genes,

respectively, whereas in *S. pennellii*, 3 pre-miRNAs genes are located in more than one position in the genome (Supplementary Table S7). The spe-miR169-1 is located in the chromossomes 0 and 7, the spe-miR1919 is in two different positions in the chromossome 8 and the spe-miR5368 is in the chromossomes 6, 7 and in two different positions in the chromossome 9. In addition, it was possible identify that 72 miRNAs in *S. lycopersicum* and 73 in *S. pennellii* were organized in clusters (10kb as the maximum distance between two miRNAs genes to consider them clustered, see Material and Methods). Of these miRNAs in clusters, we identified 50 miRNAs in *S. lycopersicum* and 47 in *S. pennellii* that were organized in clusters, but are located in antiparallel strand (Supplementary Table S7).

All identified miRNAs were analyzed for their structural and thermodynamic characteristics. *S. lycopersicum* miRNA precursors displayed an MFE with a mean of -56.50 kcal/mol, having values between -98.2 and -21.8 kcal/mol. Other parameters as AMFE and MFEI, obtained an average of -39.38 kcal/mol and of 1.03, respectively (Supplementary Table S8). In *S. pennellii*, the pre-miRNAs showed an MFE with a mean of -55.60 kcal/mol, with values between -93.7 and -23.3 kcal/mol, the mean AMFE was -39.13 Kcal/mol and that of MFEI was 1.02 (Supplementary Table S9).

In addition, we performed statistical analyzes using thermodynamic and structural characteristics of the pre-miRNAs found in both tomato species compared to pre-miRNAs deposited in miRBase from *Solanaceae*, *Fabaceae* and *Brassicaceae* families. We compared the miRNA precursor characteristics from two tomato species (Supplementary Table S10) and *Solanaceae* family miRNA precursors (Supplementary Table S11) and no differences were observed among the characteristics analyzed ($p>0.05$). In the analysis performed among *S. lycopersicum* and *S. pennellii* against *Fabaceae* and *Brassicaceae* families, the pre-miRNA characteristics were significantly different ($p<0.05$).

3.2.3.1 Characterization of tomato miRNAs

Among the 172 miRNAs families identified in the two species of study, 71 were found in both tomato species. Of all 101 different miRNAs families indentified of *S. lycopersicum* and *S. pennellii*, we highlighted 10 families for more in-depth

characterization since MIR165/166, MIR167, MIR393, MIR530, MIR827 and MIR828 families are miRNAs conserved in plants and the MIR7983, MIR7990, MIR8011 and MIR8025 families were identified for the first time in *S. lycopersicum* and *S. pennellii*. For each of these families, we analyzed the conservation of sequences and phylogenetic distributions, as well as their putative target mRNAs.

We identified 8 precursors miRNAs in MIR165/166 family, 6 in MIR167 and MIR7983, 3 in MIR7990, 2 in MIR8011 and 1 in MIR393, MIR530, MIR827, MIR828 and MIR8025 families of *S. lycopersicum* (Supplementary Table S5). In turn, in *S. pennellii* were identified 7 pre-miRNAs in MIR7983 family, 6 in MIR165/166, 5 in MIR167, 3 in MIR8011, 2 in MIR7990 and 1 precursor sequence in MIR8025, MIR393, MIR530, MIR827 and MIR828 (Supplementary Table S6). We also identified mature miRNAs in these families, including 12 in MIR7983, 10 in MIR167 and MIR165/166, 3 mature sequences in MIR7990 and MIR8011, 2 in MIR393 and MIR827, in addition to 1 in each family MIR530, MIR828 and MIR8025 of *S. lycopersicum.* In *S. pennellii*, 14 mature miRNAs were found in MIR7983, 9 in MIR167, 10 in MIR165/166, 5 in MIR8011, 2 in MIR393, MIR828, MIR827, MIR7990, MIR8025 and 1 sequence in MIR530.

The precursor and mature miRNAs identified in our work presented great conservation in their sequences and secondary structures in relation to their orthologs, especially in the miRNAs mature region. As it was the case for the Sly/SpeMIR167 (Figure 4), Sly/SpeMIR165/166 (Figure 5 and Supplementary Figure S2), Sly/SpeMIR393 (Supplementary Figure S3), Sly/SpeMIR530 (Supplementary Figure S4), Sly/SpeMIR827 (Supplementary Figure S5), Sly/SpeMIR828 (Supplementary Figure S6), Sly/SpeMIR7983 (Supplementary Figure S7), Sly/SpeMIR7990 (Supplementary Figure S8), Sly/SpeMIR8011 (Supplementary Figure S9) and Sly/SpeMIR8025 families (Supplementary Figure S10).

The analysis of the MIR167 family showed a phylogenetic tree distributed in five distinct clades. The miRNAs from *S. lycopersicum* and *S. pennellii* were grouped together with miRNAs from *Solanaceae* species (Supplementary Figure S11). The phylogenetic tree of MIR165/166 family displayed two distinct clades of *Eudicot* and *Monocotyledon*. The miRNA sequences from both tomato species were distributed within *Solanaceae* in *Eudicot* clade (Figure 6). In the phylogenetic

trees of Sly/SpeMIR393 (Supplementary Figure S12), Sly/SpeMIR530 (Supplementary Figure S13) and Sly/SpeMIR827 (Supplementary Figure S14) were also distribued in two clades of *Eudicots* and *Monocotyledons* and the were observed miRNAs from tomato species within *Solanaceae* clade. The phylogenetic tree of Sly/SpeMIR828 family showed ten clades of different families of *Eudicots* (Supplementary Figure S15).

3.2.3.2 miRNAs target genes of *S. lycopersicum* and *S. pennellii*

To understand the putative roles of miRNAs in tomato, we identified their target genes. We identified 2471 different miRNA target genes from a total of 4197 in *S. lycopersicum* for 343 mature miRNAs (Supplementary Table S12) and 3462 different targets from a total of 5768 in *S. pennellii* for 388 mature miRNAs (Supplementary Table S13).

Notably, the Sly/SpeMIR167 family miRNAs showed 247 different target transcripts, being 37 of SlyMIR167 and 210 of SpeMIR167 family. Among these targets are: putative zinc finger in N-recognin (UBR box), retrotransposon gag proteins, magnesium transporter NIPA, annexin p34, BZIP transcription factor, cytochrome P450, RING/U-box superfamily protein, kinetochore protein and a proteins class related to disease resistance (CC-NBS-LRR). In addition, were identified 74 distinct targets in Sly/SpeMIR165/166 family, with 35 of SlyMIR165/166 and 39 of SpeMIR165/166 family. Targets comprise the homeobox-leucine zipper family, especially those with the MEKHLA domain, acyl-CoA N-acyltransferases (NAT) superfamily protein and retrotransposon gag protein. Interestingly, the Sly/SpeMIR393 family miRNA targets included 23 distinct transcripts, being 12 of SlyMIR393 and 11 of SpeMIR393 family. This target genes encode carbohydrate-binding protein of the ER, lipoxygenases and proteins containing the U-box and F-box domains, as transport inhibitor response 1 (TIR1) and a auxin receptor involved in a hormone-depleting mechanism. The Sly/SpeMIR530 family displayed 31 distinct targets, with 14 of SlyMIR530 and 17 of SpeMIR530 family. Among the targets are the DEAD/DEAH box helicase, ICP0-binding domain of Ubiquitin-specific protease 7, ethylene-responsive transcription factor, adenylate isopentenyltransferase, proteins containing the AP2 domain,

NAC domain protein, MULE transposase domain and tyrosine kinase type proteins. Sly/SpeMIR827 family miRNAs obtained 50 different mRNAs targets, being 29 of SlyMIR827 and 21 of SpeMIR827 family. These comprise reverse transcriptase (RNA-dependent DNA polymerase), cytochrome P450, OTU-like cysteine protease, no apical meristem (NAM) protein, cell-wall invertase, glyoxylate reductase and SPX domain-containing family protein.

The search for Sly/SpeMIR828 target, revealed 31 different genes, with 16 target gene of SlyMIR828 and 15 of SpeMIR828 family. Among them are MYB-type DNA binding domain, syntaxin of plants 51, F9H3-4 protein, TCP transcription factor 1 and reverse transcriptase (RNA-dependent DNA polymerase). The tomato Sly/SpeMIR7983 family showed 89 target genes, being 75 of SlyMIR7983 and 14 of SpeMIR7983 family. The targets contain transcripts encoding 2C phosphatases, serine carboxypeptidase, ribonuclease T2 family, glutathione S-transferase-like protein, ENTH/ANTH/VHS superfamily protein, alpha/beta-Hydrolases superfamily protein, UDP-glucuronate 4-epimerase 4 and Myb family transcription factor family protein. In addition, Sly/SpeMIR7990 miRNAs showed 15 target transcripts different, with 13 of SlyMIR7990 and 2 of SpeMIR7990 family, as GDSL esterase/lipase proteins, MADS-box transcription factor family protein, disease resistance protein (TIR-NBS-LRR class), WRKY DNA-binding protein 31, Nop53 protein, bHLH transcription factor GBOF-1 and permease family. Interestingly, we identifed 55 distinct target genes from miRNAs belonging to the Sly/SpeMIR8011 family, being 27 of SlyMIR8011 and 28 of SpeMIR8011 family. Among them, alpha/beta hydrolases family proteins, hAT family C-terminal dimerisation region, reverse transcriptase (RNA-dependent DNA polymerase), PHD-finger transcription factor, potassium transporter, ripening regulated protein and ARM repeat superfamily protein. Finally, the Sly/SpeMIR8025 family obtained the 11 miRNAs targets, with 5 of SlyMIR8025 and 6 of SpeMIR8025 family, which encode auxin response factor 9A (ARF9A), kinase proteins domain, FKBP-type peptidyl-prolyl cis-trans isomerase, NAD(P)-binding Rossmann-fold superfamily protein and telomerase activating protein Est1 (Supplementary Table S12 and Supplementary Table S13).

3.2.3.3 Expression of tomato miRNAs in *S. lycopersicum* and *S. pennellii*

We experimentally verified the expression of six miRNAs genes (miR165/166, miR167, miR530, miR827, miR828 and miR7983) in two different tissues: leaves and flowers of each tomato species. In leaves, the miR165/166 was 7.3 times more expressed in *S. lycopersicum* compared to *S. pennellii*. The miR167, miR530 and miR827 was, respectively, 26.7, 2.2 and 2.4 times more expressed in leaves *S. pennellii* compared to *S. lycopersicum* (Figure 7a). In tomato flowers, the miR167 showed an expression of 10.0 times also higher in *S. pennellii* compared to *S. lycopersicum* and the miR165/166, miR530 and miR7983 did not show a significant difference in the expression rate between the two tomato species (Figure 7b). In addition, the miR165/166 was 7.4 times more expressed in the leaves compared to the flowers and miR167, miR530 and miR7983 showed no difference in the two *S. lycopersicum* tissues (Figure 7c). Finally, the miR167 and miR530 was, respectively, 16.0 and 2.1 times more expressed in leaves than in *S. pennellii* flowers, but miR165/166 and miR7983 showed no difference in the two *S. pennellii* tissues (Figure 7d).

3.2.4 Transcriptomic changes in tomato leaves and flowers RNAseq-based

To confirm the expression of the RNA-silencing pathway components, we searched the RNAseq data of *S. lycopersicum* and *S. pennellii* publicly available in the Sequence Read Archive (SRA)[93]. The heatmap showed expression of all genes identified in the two species in the two analyzed tissues, except the *SpeEXO.2* gene that did not present expression in leaves (Figure 8, Supplementary Figure S16, Supplementary Figure S17 and Supplementary Table S14). In *S. lycopersicum* 10 (*ABH1, AGO1.1, AGO1.2, AGO10.1, AGO10.2, EXO.1, EXO.2, EXO.3, SQN.1* and *SQN.2*) of the 28 genes from the miRNA processing machinery were found to be differentially expressed (DE) between flowers and leaves. Among 10 genes DE, 8 up-regulated in flowers and 2 up-regulated in leaves, being these *SlyEXO.1* and *SlyEXO.3*. Considering the relative expression between *S. lycopersicum* flowers and leaves, *SlyAGO10.2* and *SlySQN.2* showed higher DE in flowers. When expressed in absolute expression

values (count per million - CPM), *SlyAGO1.2* was the most expressed gene both in the flower and leaf (Figure 8a, Supplementary Figure S16 and Supplementary Table S14). Similar results were found in *S. pennellii*, wherein 11 (*AGO1.1, AGO1.2, AGO10, DDL, EXO.1, EXO.5, EXO.6, EXO.8, HESO1.2, SE* and *SQN.2*) of the 30 genes identified from the same pathway were found to be DE between flowers and leaves. In this case, all the 11 genes were up-regulated in flowers, being *SpeSQN.2* and *SpeAGO10* the genes more DE in flowers compared with leaves. As regards, the absolute expression values, *SpeAGO1.2* and *SpeAGO1.1* were the genes most expressed in flowers and leaves, respectively (Figure 8b, Supplementary Figure S17 and Supplementary Table S14).

3.2.5 Validation of the tomato miRNAs in *S. lycopersicum* small RNAs libraries

To validate the miRNAs identified in this study, we retrieved 95 small RNAs libraries of *S. lycopersicum* available in the SRA and verified the presence of the mature miRNAs in each library (Supplementary Table S15, Supplementary Table S16, Supplementary Table S17 and Supplementary Table S18). A robust analysis of the presence of 285 different sequences of mature miRNAs found in *S. lycopersicum* was performed in the 95 different small RNAs libraries, in order to validate the miRNAs identified in this study. Among the 285 different mature miRNA sequences, 262 were found in at least one library analyzed and 23 mature miRNAs were not found in the searched libraries. Members of the MIR165/166, MIR167, MIR393, MIR530, MIR827, MIR828, MIR7983, MIR7990, MIR8011 and MIR8025 families were found in 69.5%, 64.2%, 43.2%, 95.8%, 27.4%, 14.7%, 62.1%, 31.6%, 54.7% and 1% of the libraries analyzed, respectively. Only one mature miRNA of the MIR7983 and MIR8025 families was not found in any studied library.

3.3 DISCUSSION

We identified 28 (*S. lycopersicum*) and 32 (*S. pennellii*) putative proteins involved in miRNAs pathway (Supplementary Table S1 and Supplementary Table

S2), which is in agreement with the description of miRNA biogenesis pathway in other plant species, such as in *A. thaliana*, *P. vulgaris* and *O. sativa*[43,92,94,95]. The presence of these proteins in different studies has shown a high conservation of the components of miRNA processing pathways in plants, performing essential functions for the post-transcriptional regulation of mRNAs in different cells[43,92]. All the proteins involved in miRNAs biogenesis were found in the two tomato species, except for the STABILIZED1 (STA1) protein that was found only in *S. pennellii*. Considering that STA1 part of a large miRNA processing/splicing complex that orchestrates pri-miRNA splicing and processing[96], this function may have been lost in the cultivated tomato as product of domestication since it is still present in the wild tomato (S*. pennellii*).

In fact, the analysis revealed that the components of this pathway were highly conserved at the amino acid level in the two species, as well as the distribution of domains, active sites location and phylogenetic distribution when compared to orthologous proteins in other plant species. This pattern was observed in both protein families, ARGONAUTE and DICER, both proteins considered to be critical in processing machinery of miRNAs in plants[47,92].

Among all proteins found, 15 and 16 proteins belong to the AGO family of *S. lycopersicum* and *S. pennellii*, respectively, compared to 19 identified in *O. sativa*[48], 17 in *P. vulgaris*[95]. In *A. thaliana* 10 AGO proteins have been found found[92,94]. Mirzaei et al. (2014) and Bai et al. (2012) found also 15 AGO proteins in *S. lycopersicum*, being all identified in this study[69,70]. However, in study of Bai et al. (2012) two classifications were different. Solyc02g069280 and Solyc03g111760 were considered by the authors to be SlyAGO3 and SlyAGO15, but in our analyzes they were classified as SLyAGO2 and SlyAGO4, respectively. Of all the AGO proteins identified in plants, only AGO1 and AGO10 showed activity in the biogenesis of miRNAs[92,94].

The conserved domains found in SlyAGO1.1/1.2, SpeAGO1.1/1.2, SlyAGO10.1/10.2 and SpeAGO10 (Supplementary Figure S1 and Supplementary Table S3) displayed the same domains and similar distribution of the domains compared to proteins from orthologous plant species[97–100]. The Piwi conserved domains of the AGO proteins showed an active site containing a DDH catalytic triad (Figure 1a), present in AGO proteins family and proteins with RNase H

function[48,94]. These results corroborated with AGO1 and AGO10 proteins found in *A. thaliana* and *P. vulgaris*[48,94,95]. The conserved domains and active sites found in Sly/SpeAGO1 and Sly/SpeAGO10 showed high conservation when compared to AGO1 and AGO10 proteins in *A. thaliana*, *O. sativa*, *S. tuberosum*, *G. Max* and *P. vulgaris*[48,95,99,101]. This high domain conservation may be directly related to the role played by AGO1 and AGO10 proteins in the miRNA processing pathway in different species.

Other important catalytic components of the miRNAs processing in plants are the DCL proteins[95,102–108]. In this study, we identified 8 and 11 putative DCL proteins of *S. lycopersicum* and *S. pennellii*, respectively. The number of DCL proteins found in tomato genome is in agreement with other plant species: 4 DCLs have been found in the *A. thaliana* genome[92,106], 6 in *P. vulgaris*[95] and in *O. sativa* were identified at least 5 DCL proteins[48,106,109]. Bai et al. (2012) and Wang et al. (2016) found only 7 DCL proteins in *S. lycopersicum*[69,71].

The DCL1 protein is the protein of the DCL family involved in the processing of miRNAs[58,110,111]. The conserved domains found in Sly/SpeDCL1 (Supplementary Figure S1 and Supplementary Table S4) was very similar to their orthologous proteins from plant species[95,106,109], suggesting a conserved function of DCL1 proteins in tomato species. According to recent studies, especially in DCL proteins, the distance between the RNase III and PAZ conserved domains is suggested to be the largest determinant of the resulting length of processed miRNAs[51,106,112]. This demonstrates the importance of the domain distribution and conservation in the performance of these proteins at the cellular level. The two RNAse III domains (RNase IIIa and RNase IIIb) found in Sly/SpeDCL1 proteins displayed an active site with the EDDE catalytic residues (Figure 1b), also identified in DCL1 proteins from other plant species[113]. These RNase III domains are required for the cleavage and processing function of dsRNAs (double-stranded RNA) in the miRNA pathway in plants[106,109].

A phylogenetic analysis of the Sly/SpeAGO (Figure 2) and Sly/SpeDCL (Figure 3) proteins was performed from their amino acid sequences, aiming at understand the evolutionary diversification of AGO and DCL proteins in the two tomato species. The distribution of the seven clades showed a relationship between some paralogous proteins specific of the AGO family, with a great

similarity among the AGO1, AGO5 and AGO10 proteins; AGO2 and AGO7; AGO6 and AGO4 corroborating the phylogenetic distribution in *A. thaliana* and *P. vulgaris*[92,95,114]. In general, the AGO proteins phylogeny distribution identified corroborates with current species protein phylogenies[115], which suggests that the conservation level of the member of the AGO family in *Angiosperms* is high. The phylogenetic tree of the AGO proteins showed a strong correlation between AGO1 and AGO10 proteins, being these two AGO proteins which participate in miRNAs pathway in plants[92,94]. AGO proteins have a key role in transcriptional and post-transcriptional silencing mediated by small RNAs in plants. The role of these proteins in miRNA regulation has been associated with the RISC complex (RNA-induced silencing complex), allowing degradation or inhibition of mRNA translation from the complementarity of bases between the miRNAs specific sequences and the target mRNA[92,94,116].

The analysis of Sly/SpeDCL proteins showed a great similarity to evolutionary tree of life of these species within each clade[115]. The distribution among the DCL family paralogs showed a strong correlation between the DCL2 and DCL4 proteins, being also close to DCL1 and further away from DCL3, corroborating with the distribution of DCL families in other plant species[48,106]. Thus, it was observed that DCL proteins of *S. lycopersicum* and *S. pennellii* are highly conserved in the same way as observed for the AGO proteins, highlighting their great importance in post-transcriptional silencing processes in plants.

The validation of the miRNAs pathway genes in libraries available in the SRA[93] showed the DE of 10 and 11 of the 28 and 30 genes identified in *S. lycopersicum* and *S. pennellii*, respectively (Figure 8, Supplementary Figure S16, Supplementary Figure S17 and Supplementary Table S14). Among the DE genes in the two species are the genes of *ABH1, AGO1, AGO10, DDL, EXO, HESO1, SE* and *SQN* family. In *S. lycopersicum*, of the 10 DE genes, 8 were up-regulated in flowers and 2 up-regulated in leaves, already in *S. pennellii* all 11 DE genes were up-regulated in flowers. This result shows a greater requirement of these genes in flowers, suggesting a great role of the miRNA in this tissue, and considering that several miRNAs targets are related to different roles in flowers[117–119]. Yamaguchi and Abe (2012) and Wang (2014) showed the important function of miR172, miR156 and miR159 in flowering time control in *A. thaliana*[118,119]. In

addition, Aukerman and Sakai (2003) demonstrated that miR172 causes early flowering and disrupts the specification of floral organism when overexpressed in *A. thaliana*[117].

In leaves, only the *SlyEXO.1* and *SlyEXO.3* genes were up-regulated whereas the *SpeEXO.2* gene presented not expression. This is because these genes were also involved in other pathways or have other functions, such as delivery of mRNAs, miRNAs and cell-specific proteins, considering that this family had greatest number of paralogous sequences[120,121]. In both species, *AGO10* and *SQN.2* were the most up-regulated genes in flowers, suggesting that the mechanism of use of these genes in flower is conserved in these two species. Ji et al. (2011) showed overlapping roles for *AGO10* and *AGO1* in the temporal regulation of floral stem cells[122]. Furthermore, Liu et al. (2014) reported that the role of miR168a in sweet orange is the accumulation of *AGO1* in leaf and fruit biology[123]. This may justify up-regulation of *AGO10* and *SNQ.2* in the leaves, considering that *AGO10* have important roles in this tissue and SQN has a direct relation with *AGO1* whereas *AGO1* has also important roles in flowers and is down-regulated by miR168 in leaves[122,123]. Considering the absolute expression values (CPM), *Sly/SpeAGO1.2* and *SpeAGO1.1* were the most expressed genes in both tissues, showing the great importance of this protein family in plant development and, consequently, in the post-transcriptional silencing machinery using miRNAs[124].

As for miRNAs sequences, we identified 343 and 388 mature miRNAs, 226 and 234 precursor miRNAs, distributed in 87 and 85 distinct miRNA families, besides 4197 and 5768 target genes in the *S. lycopersicum* genomes (Supplementary Table S5) and *S. pennellii* (Supplementary Table S6), respectively. In addition to predicting previously reported miRNAs, our study identified many additional novel miRNAs in the genomic sequences of *S. lycopersicum*, being that of the all miRNAs found, only 110 mature and 77 precursors were deposited in the miRBase (version 21)[125] (Supplementary Table S5). Thus, we identified 233 new mature miRNAs, 149 new precursors contained in 41 miRNAs families in comparison with miRNAs deposited in miRBase.

Some studies searched also miRNAs in *S. lycopersicum,* such as Moxon et al. (2008) that found only 30 miRNAs family, Yin et al. (2008), Kim et al. (2011),

Din and Barozai (2014), Luan, Wang and Liu (2014) and Fan et al. (2015) detected 21, 12, 109, 14 and 218 miRNAs, respectively[73–75,81,126]. In addition, other works found only six miRNAs responsive to long-term RPM-treatment[88], 69 miRNAs families link with phosphate and mycorrhizal signaling[82], 112 mature miRNAs responsive with curl *New Delhi virus* (ToLCNDV)[76], 143 miRNAs associated with *Botrytis cinerea* infection[83], 95 miRNAs salt-induced stress responsive[79] and only 69 putative miRNAs associated to biotic stress[80]. Further, our study identified 126 new mature miRNAs, 94 new precursors contained 29 miRNAs families of the *S. lycopersicum* in comparison with studies published to date[7,74–76,78,81,88,126–134]. Moreover, we identified for the first time in the literature mature miRNAs and their precursors in *S. pennellii* (Supplementary Table S6).

The miRNA precursor genes localization and distribution in *S. lycopersicum* and *S. pennellii* genomes showed that 86.73% and 81.59% of the genes were found in intergenic regions, respectively, and that, in *S. pennellii*, 3 them (spe-miR169-1, spe-miR1919 and spe-miR5368) are located in more than one position in the genome (Supplementary Table S7). This high percentage of intergenic miRNAs was also found in other plants as *A. thaliana, P. trichocarpa, O. sativa, P. vulgaris, Sorghum bicolor* and *Catharanthus roseus*[37,95,97,135–138]. Some of the miRNAs genes identified were organized in clusters (72 in *S. lycopersicum* and 73 in *S. pennellii*). The presence of miRNAs genes distributed in clusters in other plants has been reported before, e.g. 54 miRNAs in clusters were found in *A. thaliana*, 40 in *P. trichocarpa*, 103 in *O. sativa*, 32 in *S. bicolor*[138] and 25 in *P. vulgaris*[95]. Furthermore, 50 miRNAs genes in *S. lycopersicum* and 47 in *S. pennellii* also were organized in clusters but in antiparallel strand, agreeing with other plant genomes deposited in miRBase (version 21), such as the miR399a and miR399e from *O. sativa*, miR169e and miR169d from *A. thaliana* and miR167e and miR167i from *G. max*[125].

The structural and thermodynamic characteristics miRNAs of the *S. lycopersicum* and *S. pennellii* were similar to those reported in other plant studies[139–142]. In plants, the values for MFE in precursor miRNAs are typically smaller than -18kcal/mol[142]. Furthermore, studies have shown that the sequences of RNAs with mean AMFE -45.93 ± 9.43 kcal/mol are considered real miRNAs, knowing that these AMFE values found in miRNA precursors had a higher

negative value than in the other classes of non-coding RNAs, for example tRNAs and rRNAs. MFEI values with a mean value of 0.97, above 0.85 were suggested for potential precursors of plants miRNAs, which distinguishes them from other RNAs, corroborating with our results[139].

The statistical analyzes using thermodynamic and structural characteristics of the tomato pre-miRNAs, comparing the two tomato species (Supplementary Table S10) and *Solanaceae* family (Supplementary Table S11) showed no differences between the groups (p>0.05). Both displayed high conservation and similarity among pre-miRNAs from *S. lycopersicum*, *S. pennellii* and also species belonging to the *Solanaceae* family. However, the results among *S. lycopersicum* and *S. pennellii* against *Fabaceae* and *Brassicaceae* families were statistically significant (p<0.05), suggesting a great evolutionary conservation of the pre-miRNA characteristics within each plant family and a significant difference among different families (Supplementary Table S11). These differences using pre-miRNA characteristic were also observed using *Monocotyledons* and *Eudicotyledons*[143].

Several studies have shown the MIR165/166 and MIR167 families are highly conserved in different plant species, such as *A. thaliana, O. sativa, G. max*, *P. vulgaris* and *S. tuberosum*[95,140,144–148]. Members of the MIR393 family were also found in *Ferns, Gymnosperms, Angiosperms, Monocotyledons* and *Eudicots*, as *A. thaliana* and *P. vulgaris*[47,56,95,110,140,149–152]. The MIR530 family was also identified in orthologous plants, such as *S. tuberosum, O. sativa, C. sinensis, P. vulgaris* and *Z. mays*[95,107,140,150,153,154]. Furthermore, *P. trichocarpa, O. sativa, Z. mays, S. tuberosum, A. thaliana* and *Brassica spp* also possess miRNAs of the MIR827 family in their genomes[140,151,155–157], and studies have demonstrated the presence of miRNAs of the MIR828 family in other species as *A. thaliana*, *O. sativa, P. vulgaris, V. vinifera* and *Z. mays*[95,150,152,158–161]. On the other hand, the MIR7990 and MIR8025 families were identified in *S. tuberosum*[125,157], MIR7983 in *Solanum pimpinellifolium*[162] and the MIR8011 family has benn found in *Lycium chinense*[154] to date. In addition, the MIR7983, MIR7990, MIR8011 and MIR8025 families were identified for the first time in *S. lycopersicum* and *S. pennellii*, in this study, suggesting that these family can be restricted to *Solanaceae* (solanum-specific)[157].

The phylogenetic analysis performed of the MIR167 (Supplementary Figure S11), MIR165/166 (Figure 6), MIR393 (Supplementary Figure S12), MIR530

(Supplementary Figure S13), MIR827 (Supplementary Figure S14) and MIR828 miRNAs families (Supplementary Figure S15) of *S. lycopersicum* and *S. pennellii* highlighted an evolutionary distribution that highly corroborates with the accepted tree of life for plant species[163].

Several tomato miRNAs showed functions modulating important biological processes through gene expression control (Supplementary Table S12 and Supplementary Table S13). Many reports in plants demonstrate similar targets of Sly/SpemiR167, such as the proteins involved in disease resistance (CC-NBS-LRR) in *O. sativa* and the peptidase family proteins in *A. thaliana*[164]. Besides presenting other important targets of MIR167 family, as in the regulation of auxin response factors (ARF4, ARF6 and ARF8)[165–170]. The targets Sly/SpeMIR165/166 family are involved mainly with plants vascular development[171], including formation of axillary meristems, root lateral meristems, laminar outgrowth and differentiation in leaves, stems, and roots[145,172–176]. Several studies have also identified targets of miR165/166 in *A. thaliana* and *O. sativa*, agreeing with our results, also showing a great conservation of function in this family in plant miRNAs, as in retrotransposon, homeobox-leucine zipper family and kinase family proteins[100,146,164,172–174,177].

Interestingly, the Sly/SpeMIR393 family act on important proteins that regulate hormone-sensitive signaling in plant development[178–182]. The targets found for Sly/SpeMIR393, mainly the TIR1 proteins, are in line with with studies in *A. thaliana, O. sativa, Z. mays, P. vulgaris, Hordeum vulgare, Gossypium hirsutum* and *M. truncatula*[56,95,140,151,164,178–180,183–186]. In barley the miR393 acts as an integrator of environmental cues in auxin signaling, being able to act in approaches related to the aluminum toxicity[186]. In additional, the miR393 exhibited important roles in nitrate response, defense against pathogenic bacteria and plant development[181]. The Sly/SpeMIR530 family displayed targets also found in *N. tabacum*[187] and *O. sativa*[164], as plus-3 domain containing proteins. Additionally, this miRNA family was involved in the nitrogen regulation and high salinity[188,189], being pivotal in the plant physiological response to stress[190].

Other studies also present similar targets for Sly/SpeMIR827 family miRNAs, as SPX domain-containing family protein in *A. thaliana*[164] and *O. sativa*[191]. The targets found indicated that miR827 plays a key role in plant stress adaptation, especially in nitrogen and phosphorus deficiency[192–195]. In *A. thaliana*

the MYB-type DNA binding domain was also identified as miR828 target[164]. Sly/SpeMIR828 target genes showed a role important in cell proliferation, control of apical dominance and organ symmetry, as well as senescence, such as found in studies carried out in other plants[161,192,196,197]. Therefore, the targets found in this study showed the importance of the regulation performed by miRNAs (Supplementary Table S12 and Supplementary Table S13).

Expression analysis by real-time PCR of miR165/166, miR167, miR530, miR827, miR828 and miR7983 genes in leaves and flowers of the two species studied showed interesting differences (Figure 7). The miR165/166 expression was larger in *S. lycopersicum* leaves compared to *S. pennellii*, and in *S. lycopersicum*, the leaves expressed more miR165/166 that in flowers. The predicted targets for the tomato miR165/166 families are related to the HD-Zip proteins family, which participate in secondary development and vascular differentiation. In this sense, as there was a high expression of miR165/166 in *S. lycopersicum* leaves, our findings suggest a higher regulation of secondary and vascular development in the cultivated tomato species leaves compared to the wild species. The miR165/166 also showed a high expression in rice libraries after a short duration heat stress[198], potato[157] and in leaves, stems and roots of *Poncirus trifoliate*[199]. miRNAs from this family were also associated with a phenotype diversity involved with drought tolerance[200–202]. Furthermore, Guo et al. (2016) showed that during the establishment of Chinese kale seedlings, the miR165/166 expression was also regulated, showing its relation with leaf normal development[203].

The miR167 was more expressed in *S. pennellii* leaves and flowers compared to *S. lycopersicum,* and between *S. pennellii* tissues the leaves showed bigger expression. In rice seeds[198] and in *S. tuberosum* leaves and flowers[204], miR167 was also more abundant. Unlike *Citrus grandis*, which showed a low expression of the miR167 family members in the floral developmental stages, indicating an important role in the reproductive development[205]. In addition, miR167 was shown to be responsive to heat shock in *Arabidopsis*[206] and played an important role in nitrogen stress responses, being up-regulated in maize shoots and roots[207]. Furthermore, most of the observed miR167 targets in plants were related to the hormonal pathways regulation, as in *A. thaliana*, rice and

coffee[156,208,209]. Considering that miR167 plays these important roles, such as responses to heat shock, nitrogen stress and hormonal pathways regulation, a higher expression showed in *S. pennellii* suggests a higher resistance of wild plants to these abiotic stresses.

The bigger miR530 expression in *S. pennellii* suggest an important role in the plant physiological control, mainly related with response of plants to biotic and abiotic stresses, in which case it may need a higher expression in the wild species, according to their targets[210]. This miRNAs family was also more expressed in leaves of durum wheat[200]. Similarly to miR530, the miR827 was more expressed in *S. pennellii* leaves compared to *S. lycopersicum*. The miR827 also showed high expression in rice seeds[156]. Unlike maize, which showed a suppressed expression in nitrogen deficiency, corroborating with other studies that showed a involvement of miR827 with adaptive responses to low nitrogen and phosphorus conditions, showing important role in stress adaptation[188,189,192,193,207]. The miR828 was also expressed at higher levels in active bud in *Camellia sinensis*. In addition, the MYB-like DNA binding proteins, miR828 targets showed a role in regulating transcription and nucleotide metabolism[211] and were holistically expressed in grapevine[212]. The miR828 presence showed also a likely involvement with phenylpropanoid metabolism, biotic and abiotic stress, cell differentiation and hormone responses[213].

The validation of the mature miRNAs identified in this study, used 95 small RNAs libraries of *S. lycopersicum* available in the SRA (Supplementary Table S15, Supplementary Table S16, Supplementary Table S17 and Supplementary Table S18). From the robust analysis performed, 262 mature miRNAs of *S. lycopersicum* were found in at least one library analyzed. This result showed that the methods used in this study for the miRNAs prediction is quite effective. Only 23 mature miRNAs were not found in the libraries. Among these miRNAs are sly-miR172d-4-5p, sly-miR172d-9-3p, sly-miR2111a-3p, sly-miR403a-3p, sly-miR7983-6-3p, sly-miR7992-5p, sly-miR8008b-2-3p and sly-miR8025-5p, that the other mature miRNA of their pre-miRNAs were present among the libraries, suggesting that in these specific libraries only one mature miRNA was necessarily expressed. Moreover, the non-presence of the other mature miRNAs in the analyzed libraries may be because some miRNAs are expressed only under specific conditions

and/or tissues, which were not present in these libraries[214,215]. This validation analysis of the mature miRNAs could not be performed with *S. pennellii* due to the low number of small RNAs libraries available from this species, highlighting that our study was the first to identify miRNAs in *S. pennellii*.

3.4 CONCLUSION

Considering the global importance of the tomato culture and the problems generated by the susceptibility to the pests of the cultivated tomato (*S. lycopersicum*) and the differences with the wild tomato (*S. pennellii*), the obtained results elucidated several aspects of miRNAs in these two species. Our results expand the study of miRNAs in plants by providing a better understanding of essential roles in the regulation processes based on miRNAs in tomato, their processing pathways and gene expression, as well as providing targets for future investigations.

3.5 METHODS

3.5.1 Identification of putative proteins involved in the miRNA pathway in *S. lycopersicum* and *S. pennellii*

The proteins involved in small RNA pathways in *A. thaliana* and *Solanum tuberosum* were identified and retrieved from the reference protein database (refseq-protein) available at NCBI (National Center for Biotechnology Information). These sequences were used as query sequences to search putative proteins involved in the small RNA biogenesis (including miRNAs) in *S. lycopersicum* and *S. pennellii* using BLASTp (Basic Local Alignment Search Tool) (http://blast.ncbi.nlm.nih.gov/Blast.cgi)[216,217]. Using the reference sequences, the putative sRNA pathway proteins were searched for in the two tomato species using data from *S. lycopersicum* (ITAG3.0) 29 and *S. pennellii* (Spenn_v2.0) 20 of the Sol Genomics Network (https://solgenomics.net/)[28].

3.5.2 Prediction of mature and precursor miRNAs

Initially, the *S. lycopersicum* (ITAG3.0)[29] and *S. pennellii* (Spenn_v2.0)[20] assembly genome were obtained from Phytozome v12.1 (https://phytozome.jgi.doe.gov/)[218] and PlaBi dataBase (http://www.plabipd.de/project_spenn/start.ep), respectively. Genome annotation files were also obtained from the databases of the respective species. The putative miRNAs and their precursors were searched applying the method described by De Souza Gomes et al. (2011), adapted for both species[219]. First, we obtained the genome sequences and found the potential hairpin sequences or similarity to miRNA precursor structures using Blastn (NCBI) and Einverted (EMBOSS tool) programs[220] and the parameters of 336 nucleotides maximum repeat and threshold value 25. Several filters were applied to these sequences to discard undesirable sequences such as other non coding RNAs sequences and also to hold those corresponding to the putative miRNAs. The applied filters were based on precursors miRNA conserved characteristics, as well as characteristics of other known regions and which have no potential to originate precursor miRNAs. These filters were: GC content (guanine and cytosine) between 20% to 65%, Minimum Free Energy (MFE), homology with conserved mature miRNAs, homology with repetitive regions and nonconding RNAs except miRNAs[219].

The miRBase database (version 21 - http://www.mirbase.org/)[125,221] was used to compare with the putative hairpin sequences and find novel *S. lycopersicum* and *S. pennelli* miRNAs accepting a maximum of 5 mismatches in final mature sequence. Other RNA groups such as ribosomal RNA - rRNA, transporter RNA - tRNA, small nuclear RNA - snRNA, small nucleolar RNA - snoRNA, SL RNA, SRP, and RNase P were discarded based on RFAM database version 12.0[222] and repetitive sequences were discarded using RepeatMasker 4.0.5 (http://www.repeatmasker.org/). The putative precursor and mature miRNAs identified were used for further analysis.

The pre-miRNA sequences identified in *S. lycopersicum* and *S. pennellii* were characterized according to their thermodynamic structures and parameters: Minimum Free Energy (MFE), Adjusted Minimum Free Energy (AMFE), Free

Minimum Energy Index (MFEI), Size, content of A, content of U, content of C, content of G, of GC and AU, GC ratio, AU ratio, Minimum Free Energy Ensemble (MFEE), Ensemble Diversity (Diversity) and MFE Structure Frequency in the Ensemble (Frequency). The AMFE was determined with MFE of sequence length 100 nucleotides and the MFEI, measured from the equation: MFEI = [(AMFE) × 100] / (G% + C%)][130]. The pre-miRNA secondary structure prediction, in addition to the diversity calculation, MFE, ensemble frequency and MFE of the secondary structures were performed using the RNAfold (http://rna.tbi.univie.ac.at/cgi-bin/RNAWebSuite/RNAfold.cgi). GC content and other structural properties were defined using Perl scripts.

3.5.3 Analysis of conserved domains, active sites, phylogeny, primary and secondary alignments

For the conservation analyzes of domains, active sites and structure evaluation, putative protein sequences and precursor miRNAs we used the multiple alignment by ClustalX 2.1 and ClustalW[223]. In addition, we used RNAalifold (http://rna.tbi.univie.ac.at/cgi-bin/RNAWebSuite/RNAalifold.cgi) to analyze the primary and secondary structure alignment of precursor miRNAs with their respective orthologs[223]. Adjusted parameters (gap opening: 22.50; gap extension: 0.83) were used for the multiple alignments of precursor miRNA sequences[224]. The pre-miRNAs and proteins sequences logos were originated from WebLogo 2.8.2 (http://weblogo.berkeley.edu/logo.cgi)[225].

The conserved protein domains were recovered separately to verify, through multiple alignment, the presence of important amino acid residues. In addition, PFAM family protein database (http://pfam.xfam.org/)[226] was used to find conserved domains and their putative functions. The Conserved Domain Database (CDD) (http://www.ncbi.nlm.nih.gov/Structure/cdd/wrpsb.cgi)[227] was used to identify amino acids from active sites of the putative proteins.

The phylogenetic analysis was performed using MEGA5.2 program and Neighbor-joining method for miRNA precursor sequence and also putative proteins[228,229]. The miRNAs evolutionary distance was calculated using the Kimura-2-parameter in site-replaced base units. For the putative proteins was

used the Jones-Taylor-Thornton (JTT) model[230]. A consensus tree was obtained using bootstrap of 5000 replicates for the precursor miRNAs and 1000 replicates for the proteins, representing the evolutionary history of the analyzed sequences group.

3.5.4 miRNA target prediction

The miRNA targets identified in *S. lycopersicum* and *S. pennellii* were predicted using psRNATarget tool (2017 Update) (http://plantgrn.noble.org/psRNATarget/)[231,232]. In order to obtain the false positives prediction rate lowest for miRNA target genes, the threshold was strict, being 3.0 for "Maximum expectation (Exp)". The other parameters used were the standard parameters: "Length for complementarity scoring (HSP size)" - 19 bp; "Top target genes for each small RNA" - 200; Target accessibility - allowed maximum energy to unpair target site (UPE) - 25; "Flanking length around target site for target accessibility analysis" - 17 bp before/13 bp after; "Range of central mismatch leading to translational inhibition", leading to inhibition of translation: 10-11 nucleotides. To analyze the miRNA target genes predicted in tomato, potential target candidate were retrieved by Phytozome v12.1 and Sol Genomics Network batabases.

3.5.5 miRNA expression by real-time PCR

3.5.5.1 Plant material

The plant material was harvested at the Experimental Station “HortiAgro Sementes S/A”, along to the Center of Development and Transference of Technology of the Federal University of Lavras (UFLA), at the municipality of Ijaci, MG. Leaves, flowers and fruits of *Solanum lycopersicum* and *Solanum pennellii* were harvested from three plants as biological replicates. The material was immediately frozen in liquid N_2 and stored in 50 mL tubes in -80ºC freezer until the RNA extraction.

3.5.5.2 RNA Extraction

The Total RNA was extracted using the QIAzol® Lysis Reagent (QIAGEN). Approximately 100 milligrams of tissue was grinded in liquid N_2 and transferred to a tube. 1mL of QIAzol was added and homogenized by vortex. The tubes were left at room temperature for five minutes. Afterwards, 300 µL of chloroform was added and homogenized by vortex. The mixture was left at room temperature for five minutes. Afterwards, the tubes were centrifuged at 12000 G at 4 ºC for 15 minutes, when three phases were formed, and 400 µL of the upper phase was collected and transferred to a new tube and 500 µL of Isopropanol was added and homogenized by vortex and left at room temperature for 10 minutes. The tubes were then centrifuged at 12000 G at 4 ºC for 10 minutes for precipitation of nucleic acids. The liquid was discarded and the pellet was washed with 1mL of 75% ethanol and centrifuged at 7500 G at 4 ºC for 10 minutes and the liquid was discarded carefully to preserve the pellet. Then, 500 µL of Isopropanol was added again and the steps were repeated. The pellet was dried at room temperature and then resuspended in 20 µL of autoclaved miliQ water.

The integrity of the RNA was visualized in 0.8% agarose gel, and the quantity and quality (ratio 260/280 and 260/230 between 1.8 and 2.2) were measured on Nanuvue spectrophotometer.

3.5.5.3 DNAse treatment

The Total RNA extracted was treated with the kit Turbo DNA-free™ (Life technologies™). 5 µg of RNA was used and the corresponding volume was completed to 22 µL with autoclaved milliQ water. Then, 2.5 µL of the 10x turbo DNAse Buffer and 0.5 µL of the turbo DNAse were added to each sample. The reaction was incubated for 30 minutes at 37 ºC. Afterwards, to stop the DNAse enzime activity, 2.5 µL of the DNAse Inactivation reagente was added. The samples were left at room temperature for 5 minutes, occasionally mixing the tubes, and then centrifuged at 10000 RPM for 2 minutes. After centrifugation, 15 µL were collected and transferred to a new tube. The samples were stored at -20 ºC until cDNA synthesis.

3.5.5.4 cDNA Synthesis and Relative Expression

The stem-loop method[63,233] was used for cDNA synthesis and expression analysis, following the steps described in[63,209]. In this method, three primers are needed – the stem-loop RT primer, the forward and the reverse primers. The stem-loop RT primers were designed according to Chen (2004)[233]. Sequence data are presented in Supplementary Table S19. The stem-loop primers contain 50 nucleotides, from which 44 nucleotides corresponds to a universal sequence, that in low temperatures form a stable stem-loop structure. The last 6 nucleotides at the 3' end of the stem-loop RT primer is a reverse complement of the last 6 nucleotides at the 3' end of the specific miRNA. The forward primers were designed with the exact sequence of the miRNA, excluding the last 6 nucleotides at the 3' end. To increase the melt temperature, nucleotides were randomly added (5-7 nucleotides) to the 5' end of the primer. Primer design software were used to calculate the melt temperature and verify the quality of the forward primers. The third primer is the reverse primer which is a reverse complement of the universal sequence of the stem-loop RT primer, and, therefore, is used for every miRNA.

The cDNA synthesis from total RNA (DNA-free) was performed using the *ImProm-II™ Reverse Transcriptase* (Promega). For each miRNA, 500 ng of RNA was used. The volume was completed to 7 µL with autoclaved miliQ water. To the RNA, 1 µL of oligodT primer; 2 µL of specific stem-loop RT primer (1 µM) and 1 µL of the dNTP mix were added. The samples were incubated at 70 °C for 10 min for denaturation of the secondary structures and later incubated at 4 °C for 10 min. Soon afterwards, 5 µl of Improm-II 5× reaction buffer, 2.4 µl of $MgCl_2$ 25 mM, 0.6 µl of RNase out (Invitrogen), and 1 µl of the Improm-II Reverse Transcriptase enzyme were added. The reactions were incubated in a thermocycler at 16 °C for 30 min, followed by reverse transcription of 60 cycles at 30 °C for 30 s, 42 °C for 30 s, and 50 °C for 1 s. For inactivation of the Improm-II Reverse Transcriptase enzyme, the reaction was incubated at 70 °C for 15 min. Subsequently, the reactions were stored at −20 °C.

Quantitative Real-time PCR (RT-qPCR) was performed using a standard SYBR Green PCR kit protocol on a Rotor-Gene Q (QIAGEN). The reactions were

performed in a final volume of 15 µl, using 1.5 µl cDNA, 1.5 µl of each primer at a final concentration of 1 µM, 7.5 µl of SYBR Green PCR Master Mix (QIAGEN), and 3.0 µl of water, for each reaction. The reaction was incubated at 95 °C for 5 min, followed by 40 cycles at 95 °C for 5 s and 60 °C for 10 s. Then, the samples were heated from 55 to 95 °C with an increase of 1 °C to acquire the denaturing curve of the amplified products. All reactions were run in triplicate.

The primer efficiency was calculated for each miRNA and the reference genes by a standard curve of a 1:5 serial dilution of a pool of cDNA of the respective miRNA. The primers efficiency is: miR165/166 (87%), sly-miR167 (97%), spe-miR167 (116%), miR827 (95%), miR7983(97%), miR530 (98%) and miR828 (96%).

To the relative expression experiment of the miRNAs in the selected tissues, the 1:25 dilution was chosen. To the calculation of relative expression, the normalized comparative Cq (quantitative Cycle) method was used[64], which takes into account the primers efficiency in the calculation. The normalization factor was the geometric mean of the U6 and 5.8S gene expression.

3.5.6 Expression of miRNA pathway genes in tomato RNA-seq libraries

Paired-end reads from leaves and flowers of both wild (*Solanum pennellii*) and cultivated (*Solanum lycopersicum*) tomato were retrieved from the Sequence Read Archive (SRA) under accessions numbers SRR786556, SRR786557, SRR786570, SRR786571, SRR786552, SRR786553, SRR786566, SRR786567, SRR786524, SRR786525, SRR786540, SRR786541, SRR786542, SRR786520, SRR786521, SRR786535, SRR786536, SRR786537[93]. In this way 10 libraries for *S. lycopersicum* and 8 libraries for *S. pennellii*, totalizing 77354968 paired-end reads, were used for differential expression analyses.

The quality of the libraries was evaluated using FastQC software[234]. Adapters were identified using minion[235] and removed with Trimmomatic[236] as well as reads with quality score and length below 20 and 35 bp, respectively. After quality control, 71703462 paired-end reads were used as input to STAR mapper tool (version 2.5.3a)[237] with default parameters to alignment against their respective genomes (*S. lycopersicum* version 3.2 and *S. pennellii* version 2.0)

retrieved from the Sol Genomics Network[28]. Approximately 88% and 87% of the *S. lycopersicum* and *S. pennellii* reads were uniquely mapped to their genomes, respectively.

The libraries were then sorted by query name using picard tools (version 2.18.0), and for each of them, raw read counts were obtained using the python script htseq-count (version 0.7.2)[238]. Differentially expressed (DE) genes were identified using the Bioconductor R package edgeR by comparing the normalized number of reads aligned to each gene in different tissues[239,240]. Benjamini and Hochberg's false discovery rate (FDR) below 0.05 and minimum fold change of two were the parameters used to consider a gene DE[241].

3.5.7 miRNAs in *S. lycopersicum* small RNAseq libraries

3.5.7.1 Sequencing analysis

95 raw small RNA data files were retrieved from NCBI Sequence Read Archive (SRA) with different accession number (Supplementary Table S15, Supplementary Table S16, Supplementary Table S17 and Supplementary Table S18). The library qualities were evaluated using FastQC software[234], adapters were removed with Trimmomatic[236] discarding reads with quality score below 20 and length less than 17 nucleotides and longer than 30 nucleotides. The filtered sequences were mapped and quantified using miRDeep2[242]. miRDeep2 and perl scripts were used to on each sequence separately to generate the numbers of the reads for each miRNAs identified.

3.5.8 Statistical analysis

For the statistical comparisons among the structural and thermodynamic variables of each category (species and/or families), a basic descriptive analysis was performed followed by non-parametric tests (Wilcoxon-Mann-Whitney). Median values were used to perform the statistical comparisons[243]. Statistical significance was set at $p<0.1$.

Author contributions statement

Mat.S.G., W.R.M., L.A.A.G., T.C.S.C., C.M.C. and T.C.A. proposed the research.

Mat.S.G., A.C.J., A.A.L., C.N.F.B., L.R.A. and T.C.S.C. designed the experiments. W.R.M., L.A.A.G., M.M.D., G.L.R., C.N.F.B., D.R.G.S., C.M.C. and T.C.S.C. prepared samples. T.C.S.C., T.C.A., C.M.C., D.R.G.S., C.N.F.B., M.M.D. and G.L.R. performed experiments. Mar.S.G., P.E.G., T.H.C.R. and L.R.A. performed the statistical analyzes. D.R.G.S., C.M.C., T.C.S.C., T.C.A., T.H.C.R., M.M.D.G, L.R.A. and Mat.S.G. performed bioinformatic analysis. T.C.S.C., T.C.A., C.N.F.B., T.H.C.R., A.A.L., M.M.D.G and Mat.S.G. wrote manuscripts and prepared figures. Mat.S.G. supervised the project. All authors reviewed the manuscript.

FIGURES

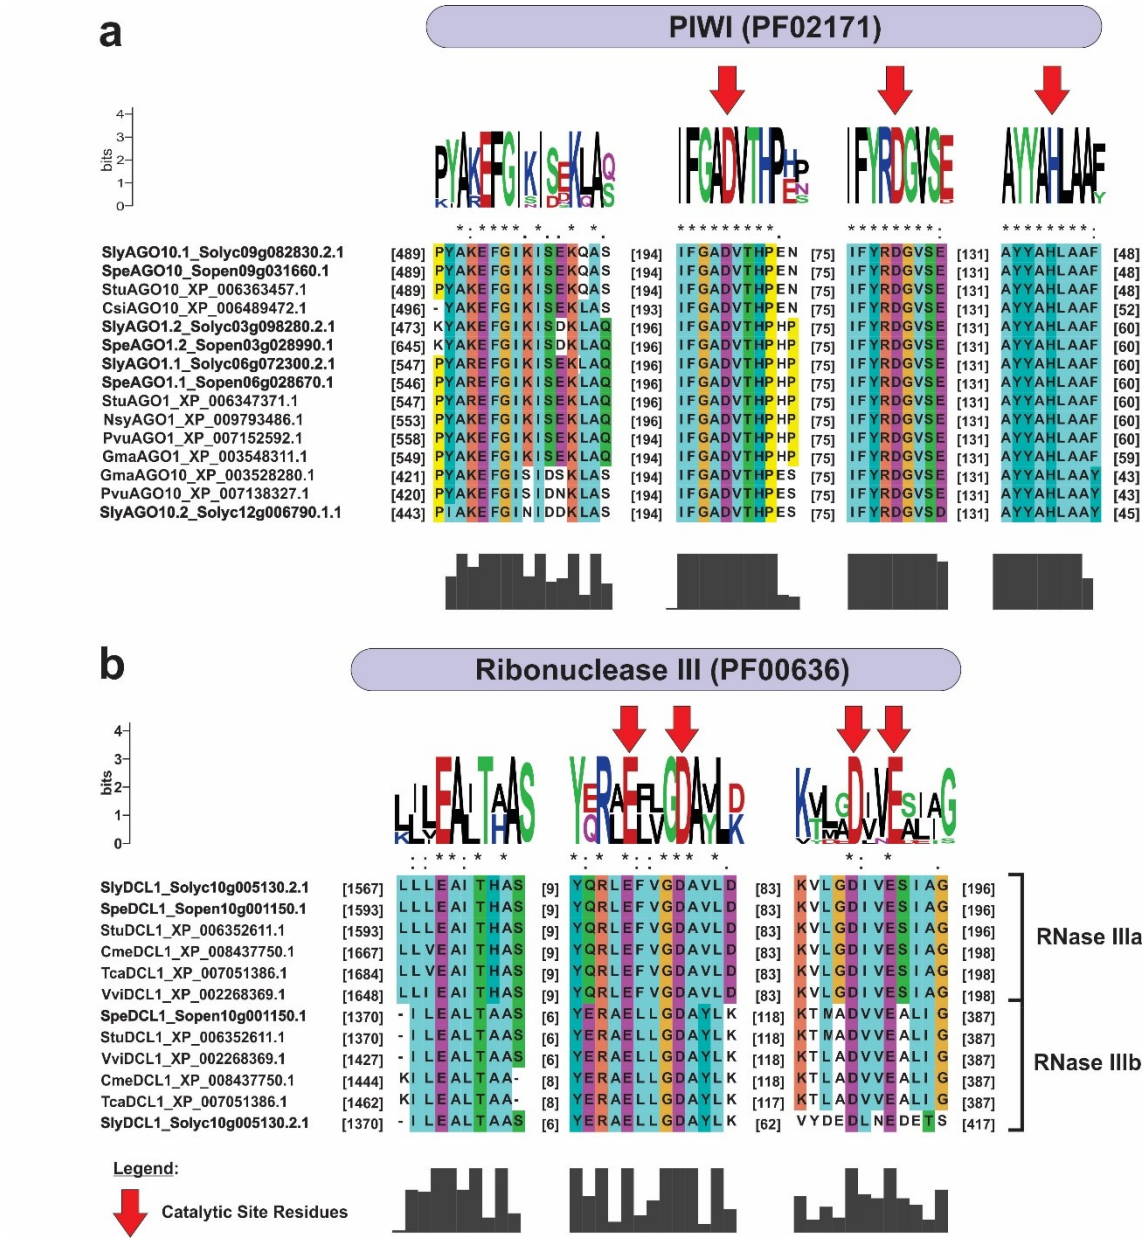

Figure 1. Weblogo analysis and sequence multiple alignment of active site amino acids and their flanking amino acid residues in the conserved domains of *S. lycopersicum, S. pennellii* and their orthologs. **(a)** PIWI domain (PF02171) from AGO proteins and **(b)** Ribonuclease III domain (PF00636) from DCL proteins. The red arrows show the amino acid residues of the active sites (catalytic triad AGO: Asp-Asp-His and DCL: Glu-Asp-Asp-Glu). The height of each amino acid symbol in Weblogo indicates amino acid residue conservation at a given position. The asterisk denotes 100% conserved amino acids at specific position. Figure 8. Heatmap analysis of the genes involved in the tomato miRNAs pathway from leaves and flowers RNA-seq libraries. Heatmap shows the expression profile of the **(a)** *S. lycopersicum* and **(b)** *S. pennellii* genes in two tissiues, being LL (*S. lycopersicum* leaves), LF (*S. lycopersicum* flowers), PL (*S. pennellii* leaves) and PF (*S. pennellii* flowers).

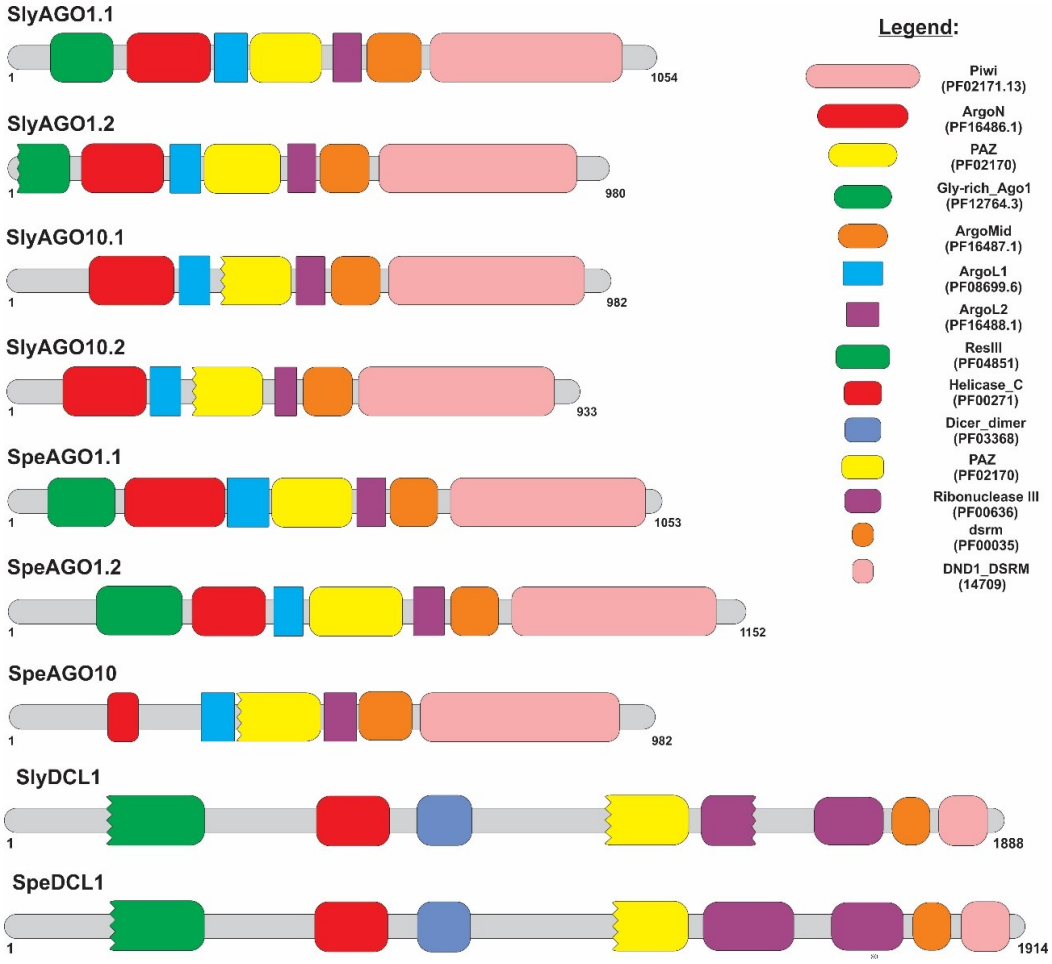
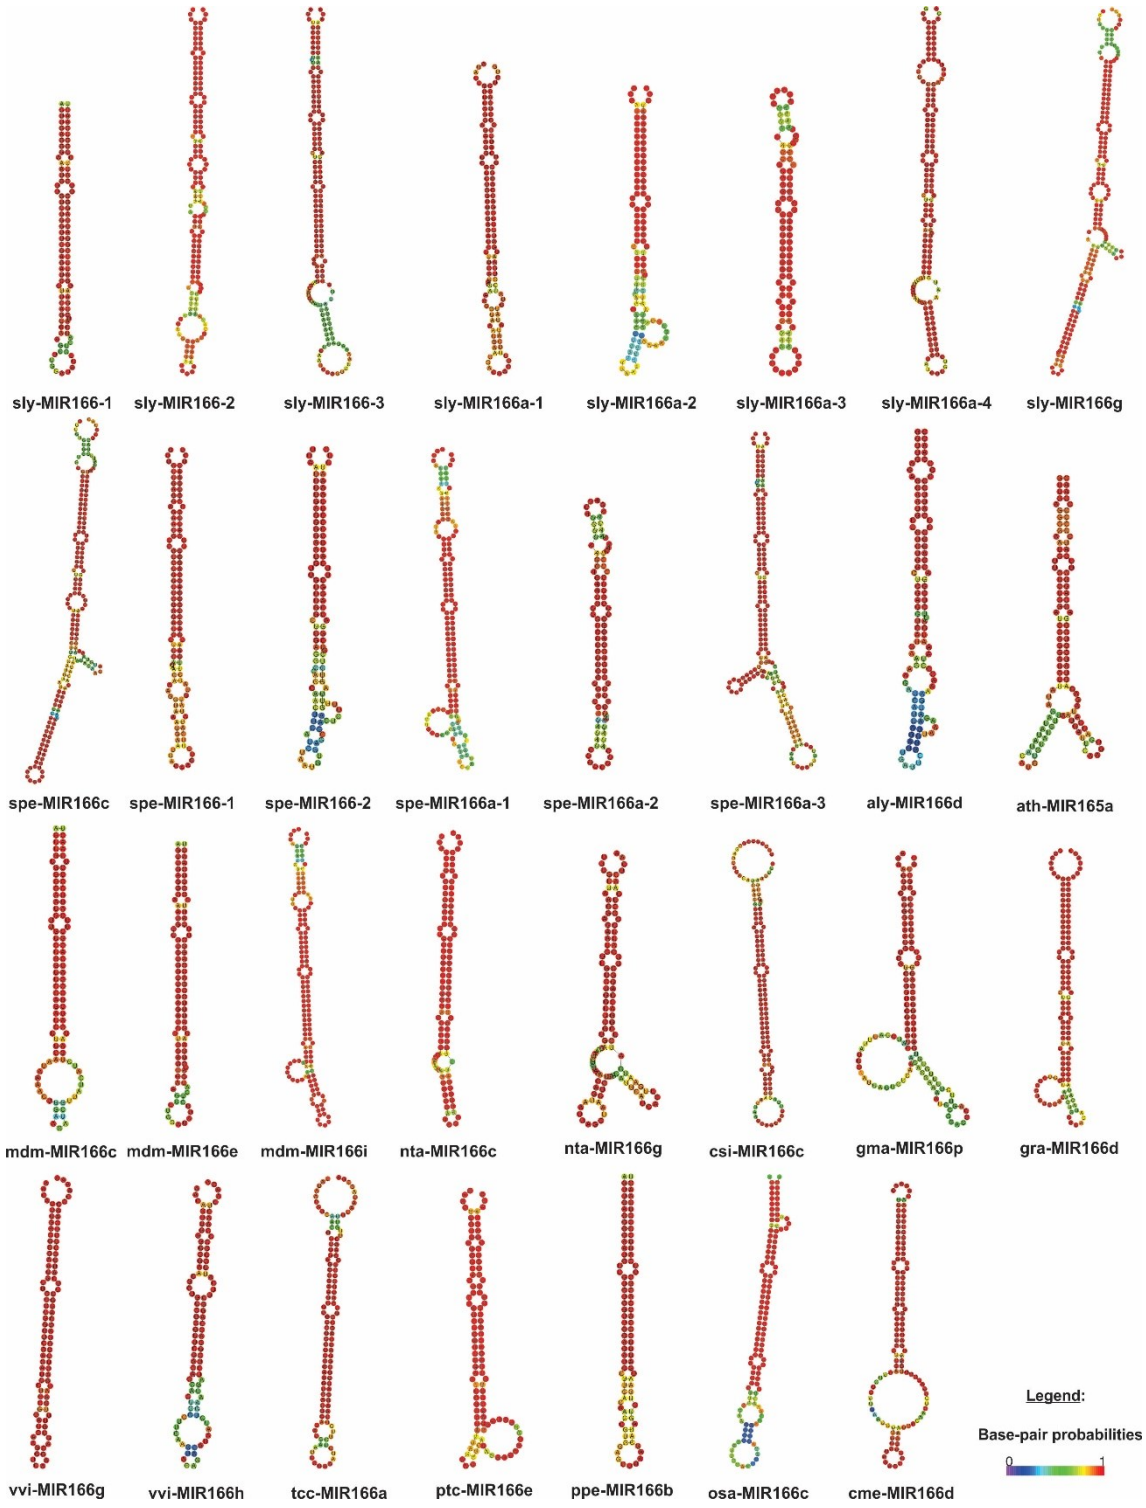
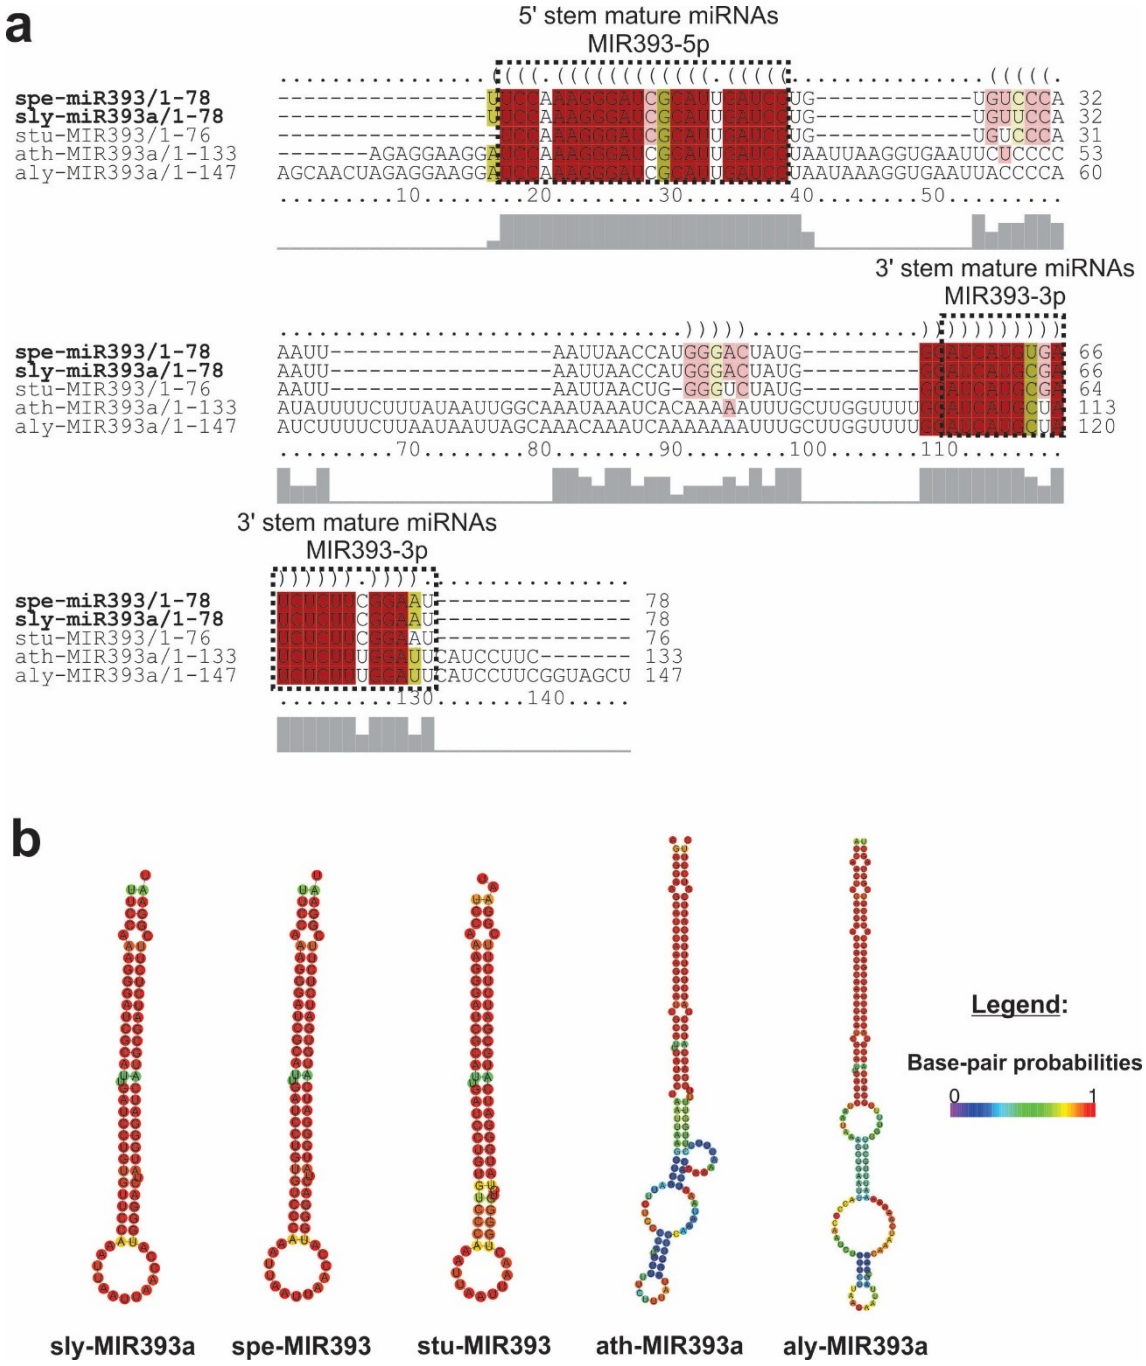
SUPPLEMENTARY FIGURES



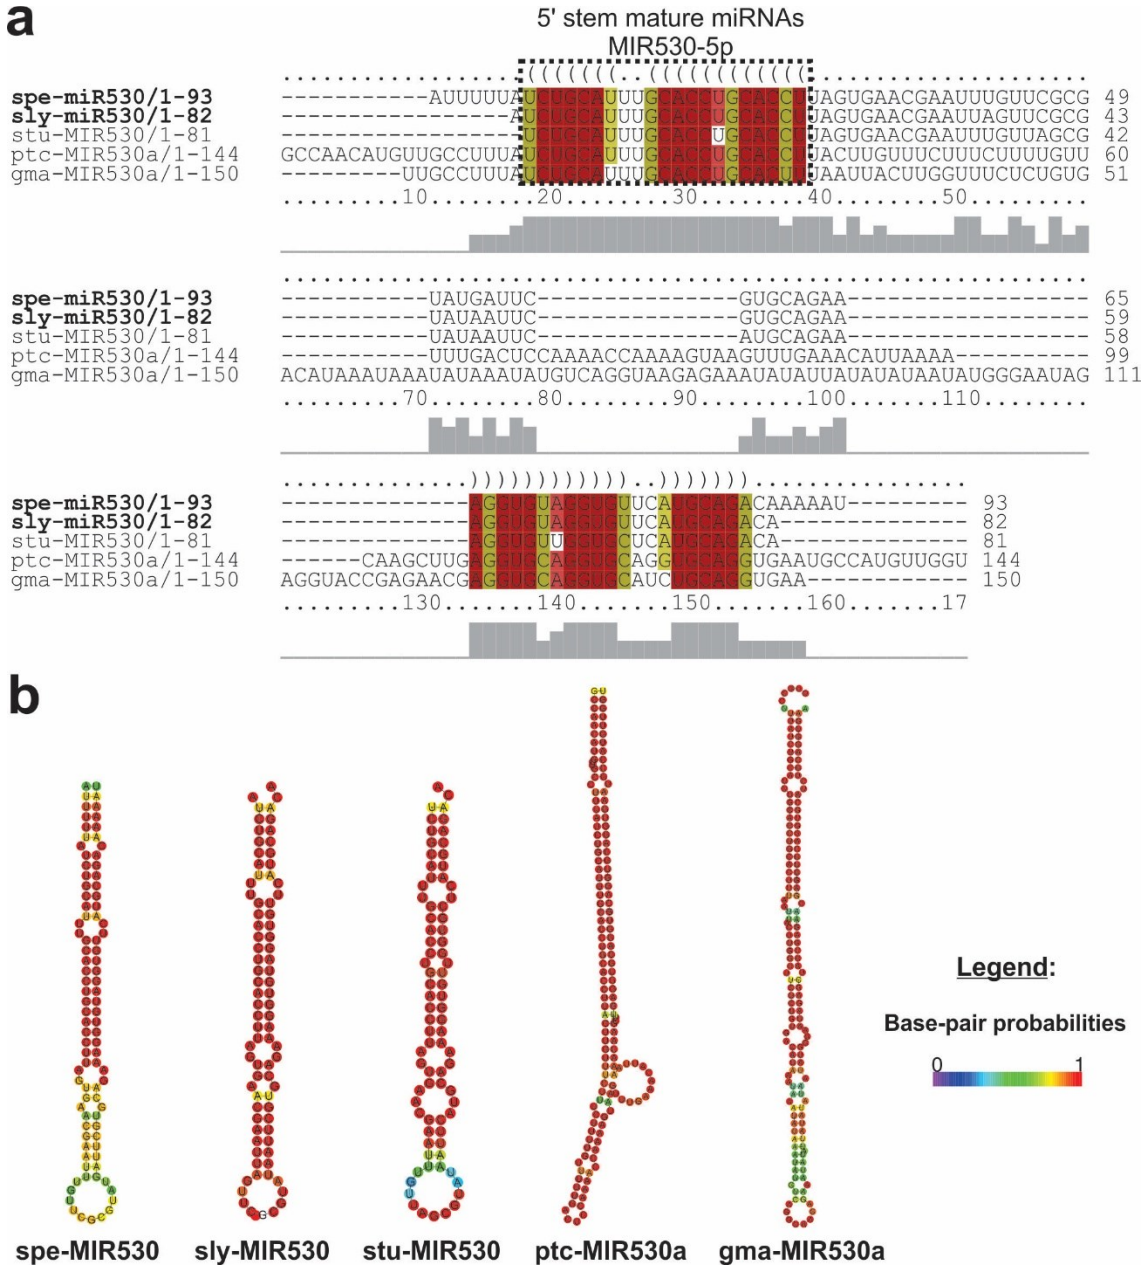
Supplementary Figure S1. Distribution of conserved domains in AGO and DCL putative proteins of *S. lycopersicum* and *S. pennellii*. The SlyAGO1.1/1.2 e SpeAGO1.1/1.2 proteins displayed the Gly-rich_Ago1, ArgoN, ArgoL1, PAZ, ArgoL2, ArgoMid and Piwi in positions 70-174, 185-328, 338-388, 394-520, 531-576, 587-661, 681-1000 / 18-100, 111-254, 264-314, 320-446, 457-502, 513-587, 607-926 e 69-173, 193-327, 337-387, 393-518, 529-575, 586-660, 680-999 / 160-272, 292-426, 436-486, 492-617, 685-759, 685-759, 779-1098, respectively. The same for SlyAGO10.1/10.2 and SpeAGO10 proteins which displayed the domains ArgoN, ArgoL1, PAZ, ArgoL2, ArgoMid and Piwi. The location these domains in SlyAGO10.1/10.2 and SpeAGO10 were at positions 127-270, 280-330, 342-462, 473-518, 529-606, 621-940 / 82-224, 234-284, 302-416, 429-472, 483-561, 575-891. The SlyDCL1 and SpeDCL1 proteins, only DCL involved in the processing of miRNAs, displayed the conserved domains ResIII (also known as DEAD-like), Helicase C, Dicer Dimer (also known as DUF283), PAZ, Ribonuclease IIIa (RNase IIIa), Ribonuclease IIIb (RNase IIIb), dsrm and DND1 DSRM, in 259-420, 656-773, 848-936, 1214-1349, 1386-1468, 1586-1699, 1726-1784, 1811-1883; e 256-420, 656-773, 848-936, 1214-1349, 1386-1534, 1612-1725, 1752-1810, 1837-1909 positions, respectively.



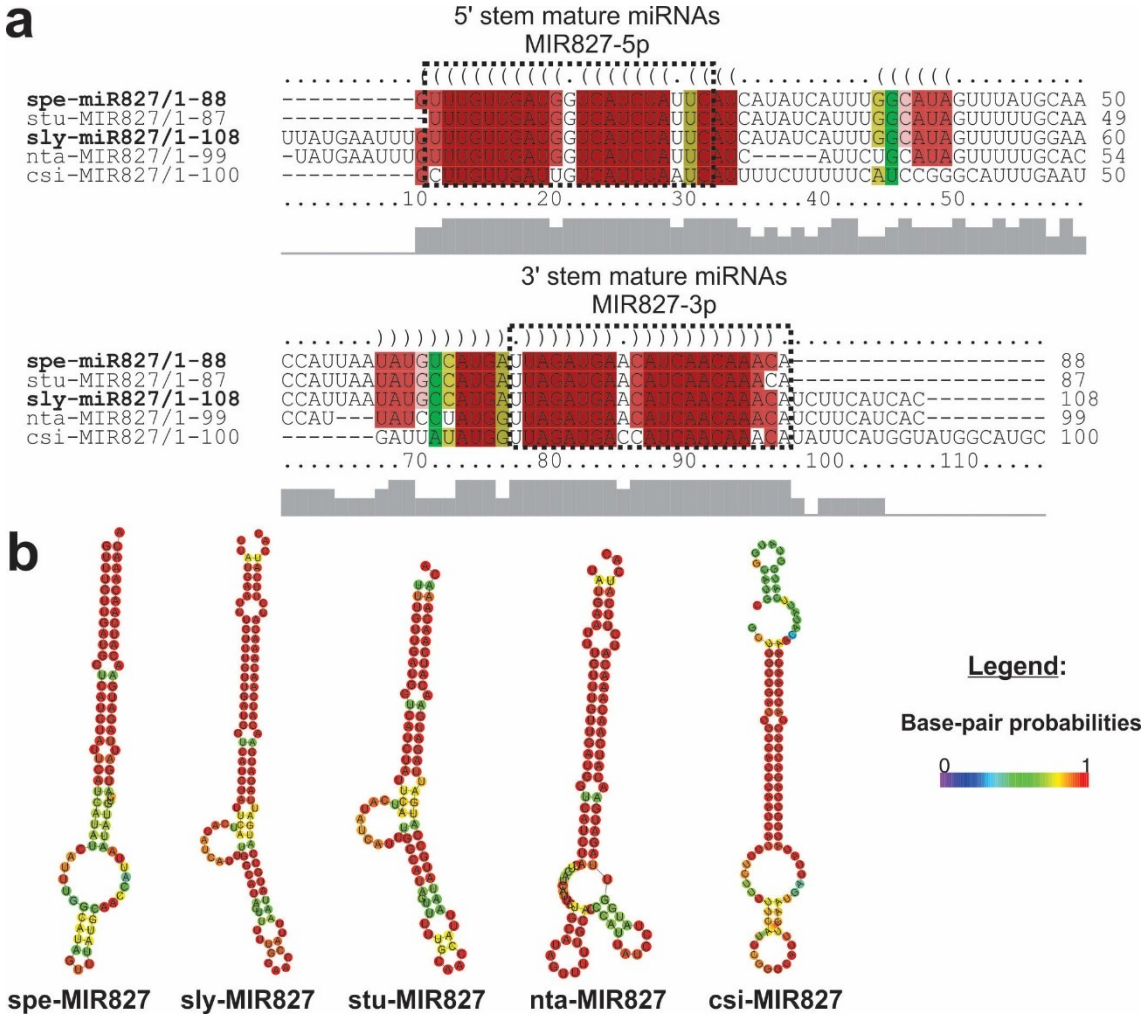
Supplementary Figure S2. Secondary structures of MIR165/166 family pre-miRNAs from *S. lycopersicum*, *S. pennellii* and their orthologs were draw by RNAfold.



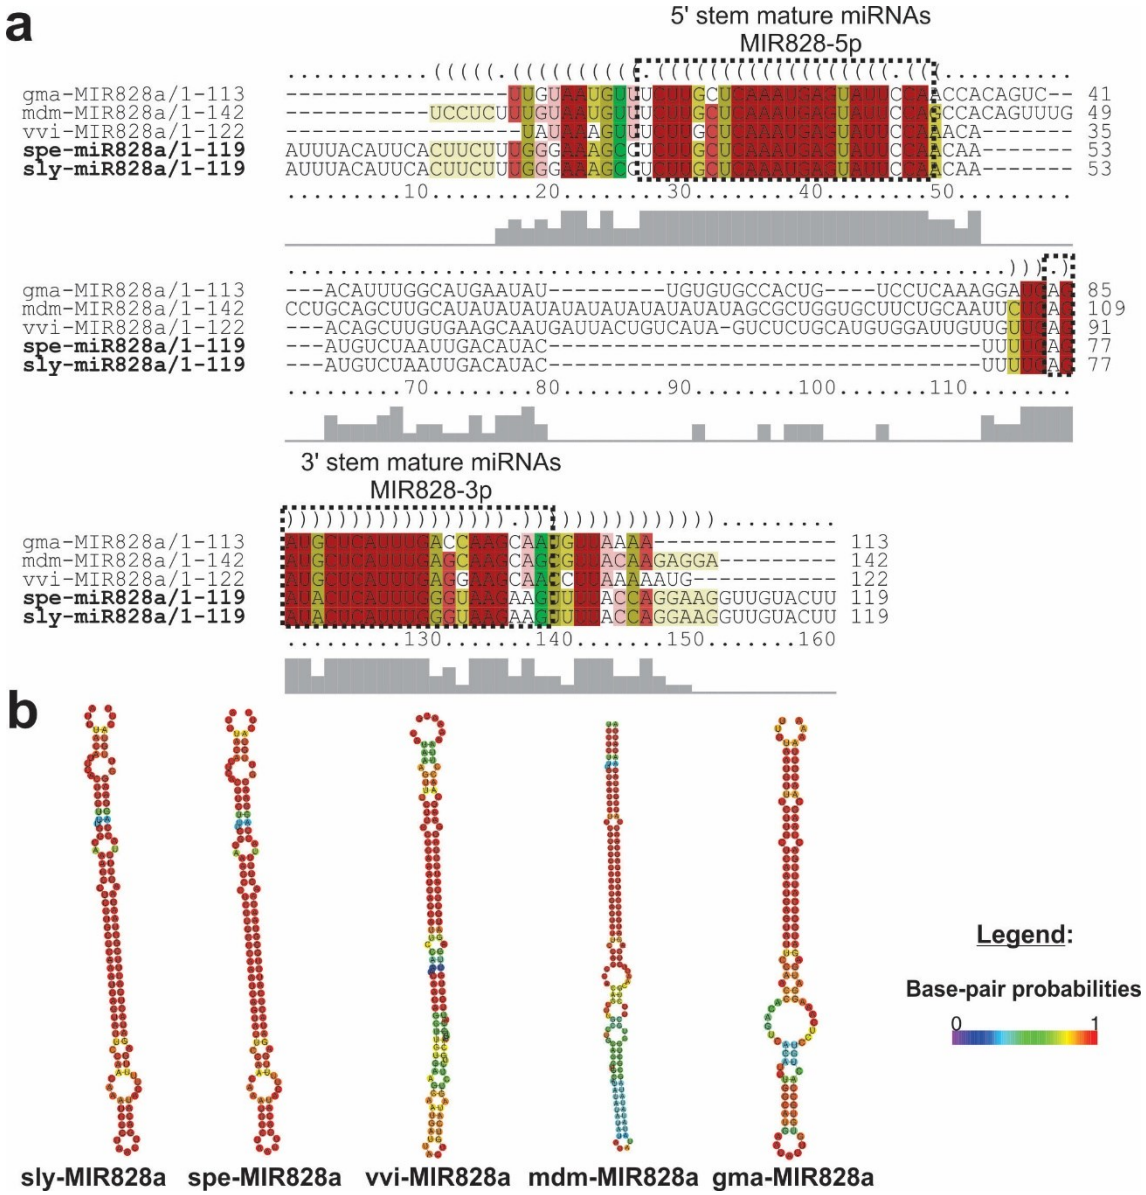
Supplementary Figure S3. (a) The high confidence of RNA alignments between MIR393 family of *S. lycopersicum* and *S. pennellii* to their orthologs were performed using RNAalifold. Mature miRNAs are shown as boxes. Brackets and colors identify matching residues in 5' and 3' stems of hairpin structures. Level of nucleotide identity is indicated below the alignment. **(b)** Secondary structures of MIR393 family from *S. lycopersicum, S. pennellii* and their orthologs were draw by RNAfold. Sly - *Solanum lycopersicum,* Spe - *Solanum pennellii,* Stu – *Solanum tuberosum,* Ath - *Arabidopsis thaliana,* Aly - *Arabidopsis lyrata.*



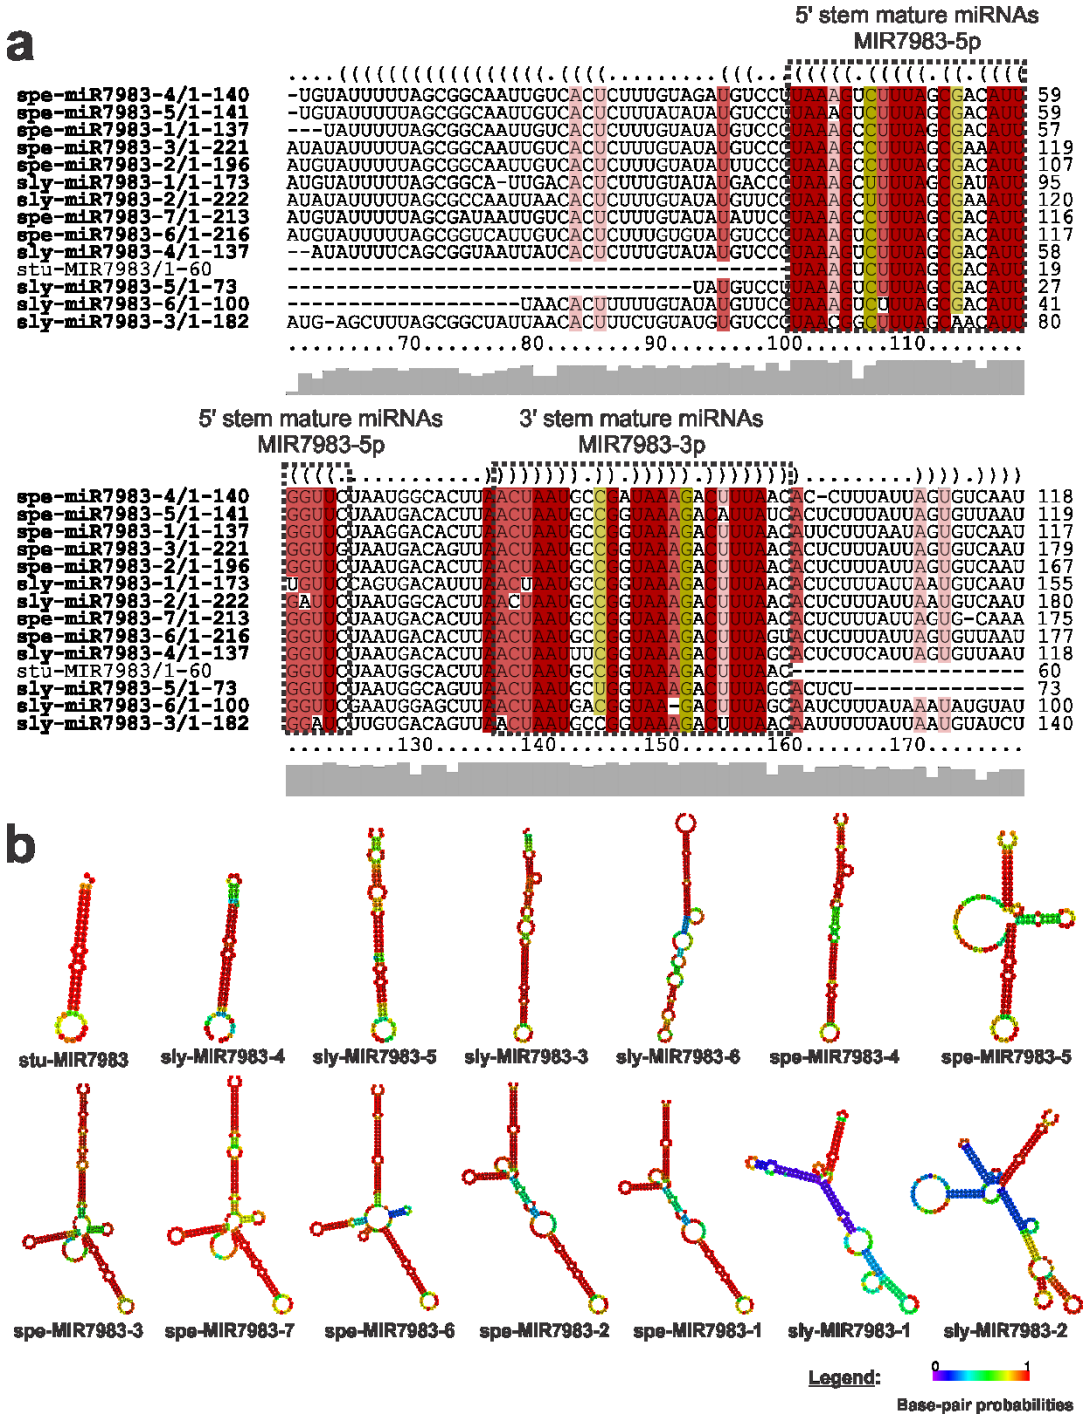
Supplementary Figure S4. (a) The high confidence of RNA alignments between MIR530 family of *S. lycopersicum* and *S. pennellii* to their orthologs were performed using RNAalifold. Mature miRNAs are shown as boxes. Brackets and colors identify matching residues in 5' stems of hairpin structures. Level of nucleotide identity is indicated below the alignment. **(b)** Secondary structures of MIR530 family from *S. lycopersicum, S. pennellii* and their orthologs were draw by RNAfold. Sly - *Solanum lycopersicum,* Spe - *Solanum pennellii,* Stu – *Solanum tuberosum,* Ptc - *Populus trichocarpa*, Gma - *Glycine max.*



Supplementary Figure S5. (a) The high confidence of RNA alignments between MIR827 family of *S. lycopersicum* and *S. pennellii* to their orthologs were performed using RNAalifold. Mature miRNAs are shown as boxes. Brackets and colors identify matching residues in 5' and 3' stems of hairpin structures. Level of nucleotide identity is indicated below the alignment. **(b)** Secondary structures of MIR827 family from *S. lycopersicum, S. pennellii* and their orthologs were draw by RNAfold. Sly - *Solanum lycopersicum,* Spe - *Solanum pennellii,* Stu – *Solanum tuberosum,* Nta – *Nicotiana tabacum,* Csi - *Citrus sinensis*.



Supplementary Figure S6. (a) The high confidence of RNA alignments between MIR828 family of *S. lycopersicum* and *S. pennellii* to their orthologs were performed using RNAalifold. Mature miRNAs are shown as boxes. Brackets and colors identify matching residues in 5' and 3' stems of hairpin structures. Level of nucleotide identity is indicated below the alignment. **(b)** Secondary structures of MIR828 family from *S. lycopersicum, S. pennellii* and their orthologs were draw by RNAfold. Sly - *Solanum lycopersicum,* Spe - *Solanum pennellii,* Vvi – *Vitis vinifera*, Mdm - *Malus domestica*, Gma - *Glycine max*.



Supplementary Figure S7. (a) The high confidence of RNA alignments between MIR7983 family of *S. lycopersicum* and *S. pennellii* to their orthologs were performed using RNAalifold. Mature miRNAs are shown as boxes. Brackets and colors identify matching residues in 5' and 3' stems of hairpin structures. ABSTRACT

BACKGROUND: Key genes control the infectivity of the *Schistosoma haematobium* causing schistosomiasis. A method for understanding the regulation of these genes might help in developing new strategies to control schistosomiasis, such as the silencing mediated by microRNAs (miRNAs). The miRNAs have been studied in schistosome species and they play important roles in the post-transcriptional regulation of genes, and in parasite-host interactions. However, genome-wide identification and characterization of novel miRNAs and their pathway genes and their gene expression have not been explored deeply in the genome and transcriptome of *S. haematobium.*

OBJECTIVES: Identify and characterize mature and precursor miRNAs and their pathway genes in the *S. haematobium* genome.

METHODS: Computational prediction and characterization of miRNAs and genes involved in miRNA pathway from *S. haematobium* genome on SchistoDB. Conserved domain analysis was performed using PFAM and CDD databases. A robust algorithm was applied to identify mature miRNAs and their precursors. The characterization of the precursor miRNAs was performed using RNAfold, RNAalifold and Perl scripts.

FINDINGS: We identified and characterized 14 putative proteins involved in miRNA pathway including ARGONAUTE and DICER in *S. haematobium*. Besides that, 149 mature miRNAs and 131 precursor miRNAs were identified in the genome including novel miRNAs.

MAIN CONCLUSIONS: miRNA pathway occurs in the *S. haematobium*, including endogenous miRNAs and miRNA pathway components, suggesting a role of this type of non-coding RNAs in gene regulation in the parasite. The results found in this work will open up a new avenue for studying miRNAs in the *S. haematobium* biology in helping to understand the mechanism of gene silencing in the human parasite *Schistosome*.

Key words: Human parasite, small RNAs, Bioinformatics, neglected diseases.

4.1 INTRODUCTION

The human schistosomiasis is a parasitic, chronic and debilitating disease caused by helminths of the *Schistosoma* genus that currently affects about 240 million people worldwide, according to the World Health Organization.[1] The countries of Africa and South America are among the most affected. In addition, 800 million people live in areas at risk of contracting the disease.[2] Five *Schistosoma* species are responsible for most of human infections: *Schistosoma mansoni*, *Schistosoma japonicum*, *S. haematobium*, *Schistosoma mekongi* and *Schistosoma intercalatum*.[1]

S. haematobium affects the reproductive and urinary system and it has been considered a major public health problem mainly in Africa.[1,3] The infection by this parasite can results in nutritional deficiencies and growth retardation, may also lead to a decrease in the cognitive system.[4] The spread of this disease occurs by fresh water and by the presence of host snails. Activities in water contact, such as agriculture, can facilitate the parasite infection.[3]

The dissemination of the disease is dependent of interaction between parasite and intermediate host. In *S. mansoni* and their intermediate host *Biomphalaria glabrata*, the interaction is complex and determined by some genes involved in the parasite infectivity and host susceptibility.[5,6] Thus, it is also suggested a complex host/parasite interation involving several genes between *S. haematobium* and its intermediate snail host, from the genus *Bulinus*. Therefore, understanding the mechanisms of gene regulation is critically important for understanding the host–parasite interactions and which genes might contribute to the infection.

The regulation of gene expression in eukaryotes comprises processes involved in translation repression and/or degradation of target genes.[7] Small RNAs, such as microRNAs (miRNAs), and their silencing pathways have been considered important in several organisms by performing a fine and specific regulation of gene expression maintaining genome integrity.[7,8]

The miRNAs are small non-coding endogenous RNAs with about 22 nucleotides in length of acting post-transcriptionally typically via imperfect complementary base pairing binding to the target genes.[7,9,10] To identify mature

miRNAs and their precursors several studies have been using experimental and computational strategies. The experimental approaches, despite presenting physical evidence of the miRNAs presence, can exclude molecules expressed in certain stages and tissues.[10,11,12] Thus, *in silico* analysis are useful for species with complete or incomplete sequenced genomes, allowing the discovery of new miRNAs using whole-genome DNA information.[11]

The genes involved in gene silencing pathway mediated by miRNAs have been described in several model organisms such as *Drosophila melanogaster*, *Caenorhabditis elegans* and *Homo sapiens*.[13,14] In addition, members of the biosynthetic pathway of miRNAs, such as ARGONAUTE and DICER, as well as miRNA molecules, have been reported in some *Schistosoma* species, including *S. mansoni*, *S. japonicum* and *S. haematobium*.[15]

Young et al., published in 2012 the whole-genome sequence of *S. haematobium*.[16] The interpretation of schistosome draft genomes has improved our understanding of the molecular biology of these parasites allowing the identification and characterization of undiscovered genes. In the face of the vastly increased importance of such non-coding RNAs in the gene expression regulation, it is important that we study mature and precursor miRNAs, as well as the genes involved in miRNA pathway in this *S. haematobium*. This might help to understand the life cycle of this parasite, its infectivity mechanism and for searching new methods of schistosomiasis control. In this work, we identified and characterized the miRNA pathway genes, the mature miRNAs and their precursors in the *S. haematobium* genome. The results found in this work will open up a new avenue for studying miRNAs in the *S. haematobium* biology in helping to understand the mechanism of gene silencing in the human parasite *Schistosome.*

4.2 MATERIALS AND METHODS

4.2.1 Prediction and characterization of genes involved in the miRNAs pathway

Firstly, to search the putative protein sequences involved in the miRNA pathway in *S. haematobium*, BLASTp tool was used (National Center for Biotechnology Information) (http://www.ncbi.nlm.nih.gov/) using as queries

sequence reference proteins from animal species, such as *D. melanogaster* and *C. elegans*, model organisms. The putative protein sequences in *S. haematobium* were found and collected from SchistoDB, *Schistosoma haematobium* Egypt genome (v 44, 2019-06-24) (http://schistodb.net). To improve the annotation of these predicted proteins involved in the miRNA pathway in *S. haematobium*, other gene prediction technique was used. The *Schistosoma haematobium* Egypt genome (v 44, 2019-06-24) was retrieved from the *Schistosoma* Genomic Resource database. To improve gene prediction of the putative genes involved in miRNA pathway in *S. haematobium* genome, single-end reads from a single cDNA library of *S. mansoni* were retrieved from SRA accession SRR629229. After quality control, approximately 63% of 36.836.649 reads were successfully mapped to the *S. haematobium* Egypt genome with STAR (v 2.5.3ab) using the parameter twopassMode.[17] The introns coordinates from this alignment were converted to GFF format to train GeneMark-ET algorithm (v 4.33).[18] In this way 19.686 putative genes were predicted. In addition, GeneMark-ES (v 4.33) was also applied to *S. haematobium* Egypt genome to predict genes without RNA-seq support, 18.622 putative genes were predicted with this approach. To identify the orthologous genes, BLAT (v 35) was applied to search query proteins against the reference genome.[19] The top 10 hits of each query were manually compared against the two sets of predicted genes using the Integrated Genome Browser (v 9.0.0).[20] In addition, Augustus web tool (http://augustus.gobics.de/) was used to improve gene prediction using the genomic locus around the BLAT results, setting the parameters to find similarities with *S. mansoni* genes. The consensus sequences, from the BLAT alignment, and the predicted genes were then aligned to their orthologous using CLUSTALX (v 2.1) (http://www.clustal.org/) and finally subjected to conserved domains searches with PFAM online tool (v 31.0) (http://pfam.xfam.org/).

The characterization and *in silico* validation of the putative protein sequences involved in the miRNA pathway in *S. haematobium* were performed using the position and the presence of the conserved domains and also of the amino acids from active sites using PFAM and Conserved Domains Database (CDD) (http://www.ncbi.nlm.nih.gov/cdd/).

4.2.2 Expression analysis

The transcripts of the genes involved in the miRNA pathway in *S. haematobium* were individually analysed using RNASeq data set, retrieved from NCBI Sequence Read Archive – SRA, of three different developmental stages of *S. haematobium*: adult female (SRR6655495), adult male (SRR6655497) and egg (SRR6655493)[16]. Quality control and adapter removal were conducted using Trimmomatic (v 0.36). Single-end reads were aligned against pre-selected sequences using bowtie2 (v 2.3.0) with the "--very-sensitive-local parameter". Alignment sam files were sorted and converted to bam files with samtools (v 1.6). Expression values were extracted from the alignment results using express (v 1.5.1) and RPKM (Reads Per Kilobase of transcript, per Million mapped reads) were calculated after library size normalization with the Bioconductor package edgeR in the R statistical environment. The results of the expression analysis were plotted in a heatmap, where the color system applied comprises an intense red color as the highest transcript expression and an intense blue color as the lowest transcript expression.

4.2.3 Prediction and characterization of mature miRNAs and their precursors (pre-miRNAs)

A robust algorithm used to predict miRNAs in *S. mansoni* genome[10] was also used for identification and characterization of mature miRNAs and their precursors in *S. haematobium* Egypt genome. The data was applied to Einverted (EMBOSS tool)[21] and BLASTN programs (http://www.ncbi.nlm.nih.gov/) to select sequences that show potential hairpin formation or similarities with precursor miRNAs. These sequences were applied in a set of filters accepting in the end of the algorithm putative real conserved miRNAs. These filters were based on conserved characteristics of precursor miRNAs and regions that have no potential formation of pre-miRNAs were discarded. The filters used were: GC content (guanine and cytosine), Minimal Energy Free (MFE), homology with mature miRNAs already identified, homology with protein coding region, homology to repetitive regions and homology with non-coding RNAs.

The miRNA cluster searching was optimized using information obtained from the position (start and the end position of the precursor miRNAs) each

miRNA identified in the *S. haematobium* Egypt genome. miRNAs found at a distance of less than 10k nucleotides downstream or upstream depending on the direction in the DNA strand were considered linked in a specific miRNA cluster. Each sequence portion was retrieved from the *S. haematobium* Egypt genome using information from the first and last nucleotides of the cluster. The secondary structure of each cluster was obtained using the RNAfold tool (http://rna.tbi.univie.ac.at/cgi-bin/RNAWebSuite/RNAfold.cgi).

miRNA sequences identified as putative real conserved miRNA precursors in *S. haematobium* genome were characterized structurally and thermodynamically using RNAfold, RNAalifold (Vienna RNA Package) (http://rna.tbi.univie.ac.at/cgi-bin/RNAWebSuite/RNAalifold.cgi) and homemade Perl scripts.[22]

4.2.4 miRNAs in *S. haematobium* Egypt small RNA-seq libraries

Two small RNA data files of adult male (SRR6655496) and adult female worms (SRR6655494) were retrieved from the NCBI Sequence Read Archive (SRA). The library qualities were evaluated using FastQC software.[23] The adapters were removed with Trimmomatic[24] discarding reads with quality score below 20 and length less than 17 nucleotides and longer than 30 nucleotides. The filtered sequences were mapped and quantified using miRDeep2.[25] miRDeep2 and perl scripts were used on each sequence separately to generate the numbers of the reads for each miRNAs identified.

4.2.5 Sequence alignments and phylogenetic analysis

The multiple sequence alignment (MSA) were performed to *S. haematobium* Egypt putative proteins involved in the miRNA pathway and also for the *S. haematobium* Egypt pre-miRNA sequences and their respective orthologs. These analyses were performed by CLUSTALX 2.0 with default parameters multiple sequence alignment of proteins and for the pre-miRNA sequences were used the following adjusted parameters: gap opening 22.50 and gap extension 0.83.

Phylogenetic analysis was performed using MEGA version X[26] and Neighbor-Joining.[27] A consensus tree was generated applying a bootstrap of

5.000 replicates for pre-miRNA sequences and 2.000 replicates for protein sequences. The calculation of their evolutionary distance was performed using Kimura-2-parameters for the pre-miRNA and JTT for protein sequences.[27]

4.2.6 Statistical analysis

For the statistical comparisons among the structural and thermodynamic variables of each category (superphylum, phylum and/or genus), a basic descriptive analysis was performed followed by non-parametric tests (Wilcoxon-Mann-Whitney). Median values were used to perform the statistical comparisons.[28] Statistical significance was set at $p<0.05$.

4.3 RESULTS

4.3.1 Identification, characterization, phylogenetic analysis of putative proteins involved in miRNA pathway

The predicted proteome version 44 of the *S. haematobium* genome obtained from SchistoDB was used to identify and characterize the predicted *S. haematobium* proteins involved in the miRNA pathway. Fourteen putative *S. haematobium* proteins involved in the miRNA pathway were identified and characterized according to their putative function based on homology, conserved domain distribution (and conservation) and protein size. These *S. haematobium* proteins were compared with their miRNA pathway orthologue proteins from related species such as *Schistosoma* species and model species (e.g. *C. elegans* and *D. melanogaster*) (Table 1). In order to confirm and improve the prediction of the proteome version 44 of the *S. haematobium* an alternative predicted genome-based proteome was performed using information from the *S. haematobium* genome and RNAseq sequences (SRR6655495, SRR6655497, SRR6655493). 18.622 putative genes were predicted with this alternative approach to predict the *S. haematobium* proteome. Comparing the proteins involved in the miRNA pathway predicted from *S. haematobium* version 44 to proteins obtained from the alternative predicted proteome only the DROSHA protein sequence was divergent. The putative DROSHA sequence predicted from proteome version 44 - SchistoDB showed 1041 amino acids in length and only one Ribonuclease III conserved

domain. The new prediction of DROSHA showed a protein with two Ribonuclease III and one DSRM conserved domains with 1581 amino acids in length corroborating with their orthologs and thus used for further analysis. Among the fourteen putative *S. haematobium* proteins involved in the miRNA pathway identified, two key protein families of the canonical miRNA biogenesis pathway were considered for the further analysis: ARGONAUTE and RNAse III proteins (DICER and DROSHA). We were able to identify and characterize in *S. haematobium* data and considered for the further analysis two AGO proteins (sht_Ago_MS3_08447/ sht_Ago_MS3_01142), two DICER proteins (sht_Dcr_MS3_05083 and sht_Dcr_MS3_09247) and one DROSHA protein (sht_Drsh_MS3_06910).

4.3.1.1 ARGONAUTE

The putative sht_Ago_MS3_08447 protein displayed only the PIWI and PAZ domains at positions 559-852 and 304-400, respectively. On the other hand, the putative protein sht_Ago_MS3_01142 showed the PAZ, PIWI, ARGOL1, ARGOL2, ARGON and ARGOMID domains. These *S. haematobium* Ago proteins and the distribution of their conserved domains corroborated with their orthologues in *S. mansoni* (Smp) and *S. japonicum* (Sjp)[15] (Figure 1).

The PIWI domain of these proteins showed a catalytic triad formed by DDH (aspartic acid, aspartic acid and histidine). In sht_Ago_MS3_08447, the catalytic triad was found at positions Asp621, Asp711 and His844. In sht_Ago_MS3_01142, the same triad was identified at positions Asp747, Asp819 and His957. Besides that, this triad showed high conservation in relation to ortholog AGO proteins (Figure 2).

The AGO protein family can be divided into two subfamilies, AGO and PIWI. AGO and PIWI orthologous proteins from animal species were used to compare with the putative *S. haematobium* AGO proteins. The organization of the AGO protein family clades in the phylogenetic analysis occurred as expected, in distinct clades, AGO subfamily grouped with AGO orthologous proteins including *S. haematobium* AGO proteins and PIWI subfamily with PIWI orthologous proteins. The distribution of the AGO and PIWI proteins from animal species corroborate with the species distribution in the tree of life (Figure 3). We observed that *S.*

haematobium putative proteins showed a suitable organization compared with their orthologs, in the Plathyhelminthe clade, with *S. haematobium, S. mansoni and S. japonicum* proteins clustering closest within the clade.

4.3.1.2 DICER and DROSHA

Two DICER proteins (sht_Dcr_MS3_05083 and sht_Dcr_MS3_09247) and one DROSHA protein (sht_Drsh_MS3_06910) were identified and characterized. The sht_Dcr_MS3_05083 displayed four domains, while sht_Dcr_MS3_09247 two conserved domains, and sht_Drsh_MS3_06910 three conserved domains. The putative sht_Dcr_MS3_05083 protein identified in the *S. haematobium* Egypt genome presented, in its structure, the conserved domains Dicer Dimer, PAZ, Ribonuclease III (Riboc I), Ribonuclease III (Riboc II), in the positions 896-1005, 1336-1508, 1926-2102, 2212-2474, respectively. The putative sht_Dcr_MS3_09247 presented only the Ribonuclease III (Riboc I) and Ribonuclease III (Riboc II) domains, in the positions 548-659 and 801-889. Finally, the putative sht_Drsh_MS3_06910 showed the Ribonuclease III (Riboc I), Ribonuclease III (Riboc II) and DSRM domains, at positions 941-1002, 1076-1229, 1258-1327, respectively, in its structure (Figure 4).

The two Ribonuclease III conserved domains identified in the putative DICER proteins (sht_Dcr_MS3_05083 and sht_Dcr_MS3_09247), showed an active site high conserved compared to their orthologs. Both domains displayed the conserved active site catalytic motif (EDDE): glutamic acid (E), aspartate (D), aspartate (D) and glutamic acid (E). The domains Riboc I in the sht_Dcr_MS3_05083 presented the catalytic residues conserved, at positions Glu2215, Asp2219, Asp2280 and Glu2283 and in sht_Dcr_MS3_09247 at positions Glu551, Asp555, Asp645 and Glu648. In the putative protein sht_Drs_MS3_06910 the catalytic residues of Riboc I domain showed in the positions Glu944, Asp948, Asp1017 and Glu1020 (Figure 5).

The phylogenetic analysis of DICER and DROSHA putative proteins displayed the evolutionary relationship with their orthologs and paralogues. The *S. haematobium* proteins clustered within Platyhelminthes clade closest to *S. mansoni* and *S. japonicum* DICER and DROSHA proteins. The phylogenetic tree

displayed two distinct clades (DICER and DROSHA clades) corroborating with the literature and the distribution of the species in the tree of life (Figure 6).

4.3.2 Expression Analysis of miRNA pathway transcripts

The genes involved in miRNA pathway identified in the genome data of *S. haematobium* were used to perform the expression analysis. This procedure occurred through submitting these transcripts individually to analyze against RNASeq data set for a library of three different stages of development in *S. haematobium,* adult female (SRR6655495), adult male (SRR6655497) and egg (SRR6655493). The heatmap showed the expression profile of the transcripts in the egg, adult female and adult male stages of the *S. haematobium* (Figure S1). The gene that showed a highest expression level was the VIG (MS3_11239) that showed a more intense red color in the heatmap for the three stages presented. The transcript of FMR1 (MS3_05484) also showed high level of expression in the three stages. The Expo1 transcript (MS3_06671) presented a high expression in egg and adult male, and a medium expression in adult female. The TSNA transcript (ID MS3_07205) presented a high expression in egg and adult female and a medium expression in adult male. The transcripts of the putative ARGONAUTE (sht_Ago_MS3_08447), showed a high level of expression in adult female and egg, and a low expression in the adult male. The others transcripts ARGONAUTE (sht_Ago_MS3_01142), DROSHA (sht_Drsh_MS3_06910) and DICER (sht_Dcr_MS3_05083 and sht_Dcr_MS3_09247), showed a low expression in all stages.

4.3.3 Identification and characterization of precursor and mature miRNAs in *S. haematobium* Egypt genome

We identified in the *S. haematobium* Egypt genome 149 mature miRNAs and 131 pre-miRNAs (Table S1). Regarding the miRNA precursor localization in *S. haematobium* Egypt genome, 98 (73.68%) were found in intergenic regions and 34 (26.32%) intragenic (Table S2). In addition, it was possible identify that 15 pre-miRNAs were organized in clusters (10kb as the maximum distance between two miRNAs genes to consider them clustered), such as sht-miR-71a/sht-miR-2a-1/sht-miR-2b/sht-miR-2e (Figure S2).

All pre-miRNAs identified were analyzed for their structural and thermodynamic characteristics. The *S. haematobium* Egypt pre-miRNAs displayed MFE with an average of -25.3 kcal/mol, with values between -48.5 and -18.5 kcal/mol; AMFE values averaging -27.91 kcal/mol and MFEI with -0.752 kcal/mol (Table S3).

In addition, we performed statistical analyses using thermodynamic and structural characteristics of pre-miRNAs found in *S. haematobium* Egypt compared to pre-miRNAs deposited in the miRBase from Ecdysozoa, Cnidaria, Polifera and Schistosoma clades (Table S4). We compared the miRNA precursor characteristics from genus *Schistosoma* miRNA precursors and no differences were observed among the characteristics analyzed ($p>0.05$). On the other hand, in the analysis performed among *S. haematobium* Egypt against Ecdysozoa, Cnidaria and Porifera phylum, the pre-miRNA characteristics were significantly different ($p<0.05$).

Results obtained using SRA data from male (SRR6655496) and female worms (SRR6655494) evidenced that all mature miRNAs were found in the genome, although some were not expressed in the libraries used for analysis. On the other hand, highly conserved miRNAs such as bantam, miR-2, let-7, miR-71, miR-125, miR-124 and miR-10 showed a greater amount of reads found in SRA data. In addition, some miRNAs were found only in the adult males library, suggesting possible targets for further studies (Table S5).

Of all precursor miRNAs, four families (miR-10, miR-8, miR-2 and miR-7) were selected to further analysis once they showed high conservation based on structural, thermodynamic characteristics and their phylogenetic distribution.

4.3.3.1 sht-miR-10

The sht-miR-10 precursor found in this study, showed two mature miRNAs, sht-miR-10-3p and sht-miR-10-5p. The sht-miR-10 precursor sequence presented a great conservation in the primary and secondary structures when compared to the ortholog sequences used for these analyses, as *S. mansoni, S. japonicum, Apis mellifera* and *D. melanogaster* (Figures 7 and 8).

Three clades were observed in the tree generated by phylogenetic analysis. The first clade was identified as Lophotrochozoa, showing sequences of Mollusca

and Platyhelminthes organisms. The second clade, called Ecdysozoa, was composed by arthropods organism sequences and the third clade presented Echinodermata organisms. This distribution showed similarity to the tree of life, where *S. haematobium* Egypt remained alongside others flatworms (Figure 9).

4.3.3.2 sht-miR-8

One precursor of miR-8 family was identified in the *S. haematobium* Egypt genome, sht-miR-8. Two mature miRNAs from this precursor also were found and named sht-miR-8-3p and sht-miR-8-5p. These sequences presented high conservation in relation to their orthologs in *S. mansoni, S. japonicum, Bombix mori, Heliconius melpomene, Anopheles gambiae, Daphnia pulex, Nasonia vitripennis, Ixodes scapularis* and *Lottia gigantea*, both for analyses of primary structure and secondary structures (Figures S3 and S4).

The phylogenetic analysis generated a tree divided in two clades: Lophotrochozoa and Ecdysozoa. The *S. haematobium* Egypt sequences were found closer to the main orthologs species, *S. japonicum* and *S. mansoni*, in the clade Lophotrochozoa, as well as organisms belonging to the Mollusca phylum. For the Escysozoa clade, the arthropod organisms were the only representative of this group. According to the conservation of the pre-miRNA sequences of these species, this distribution relation is also observed in the animal's tree of life (Figure S5).

4.3.3.3 sht-miR-2

In miR-2 family of *S. haematobium* Egypt were identified five precursor miRNAs (sht-miR-2a-1, sht-miR-2a-2, sht-miR-2b, sht-miR-2c and sht-miR-2e) and nine mature miRNAs: sht-miR-2a-1-3p, sht-miR-2a-1-5p, sht-miR-2a-2-3p, sht-miR-2b-3p, sht-miR-2b-5p, sht-miR-2c-3p, sht-miR-2c-5p, sht-miR-2e-3p and sht-miR-2e-5p.

The *S. haematobium* Egypt miRNAs from this family exhibited high conservation as mature miRNAs when compared with their orthologs in *S. mansoni* and *S. japonicum* (Figure S6). It was possible to observe that there is a great similarity between the secondary structures of the pre-miRNAs within the same family, as well as between *S. haematobium* and *S. mansoni* (Figure S7).

The tree generated from the phylogenetic analysis of miR-2 family showed a distribution into two clades. The clade Lophotrochozoa was composed by the Mollusca, Annelida and Platyhelminthe phylum, while the Ecdysozoa clade presented Arthropod organisms as its representative. Besides that, there was a correct grouping between all precursors sequences of this family (sht-miR-2a-1, sht-miR-2a-2, sht-miR-2b, sht-miR-2c and sht-miR-2e) with their respective orthologs species, mainly *S. mansoni* and *S. japonicum* (Figure S8).

4.3.3.4 sht-miR-7

Two precursor miRNAs of miR-7 family were identified: sht-miR-7 and sht-miR-7b. Besides that, three mature miRNAs also were found (sht-miR-7-5p and sht-miR-7b-5p) in *S. haematobium* Egypt genome. In the primary structure results of miR-7 family were observed a high conservation between the nucleotide sequences of *S. haematobium* miRNAs and their orthologs (Figure S9). The analysis performed for pre-miRNA secondary structures of miR-7 family also evidenced a great conservation between the *S. haematobium* miRNAs and their orthologous organisms (Figure S10).

Three well defined clades were observed in the phylogenetic analysis performed for sht-miR-7 family: the Deuterostome group and the Lophotrochozoa and Ecdysozoa clades formed the Protostome group. The first group was composed of Chordata and Hemichordata phylum, while the second group had the presence of flatworms and arthropod organisms. The species classification showed by this analysis corroborates with the distribution found in the animal tree of life (Figure S11).

4.4 DISCUSSION

The first version of *S. haematobium* genome published by Young et al. (2012) provided the conditions to researchers to study the genome and we were able to apply this robust analysis to identify and characterize miRNAs, and the putative proteins involved in miRNA processing pathway in the genome of this human parasite.[16] The miRNAs and proteins of their biosynthetic pathway were described in several organisms, including plants and animals. In animals, in the

model organisms *D. melanogaster* and *C. elegans,* were found mature and precursor miRNAs, pathway proteins and miRNA target genes.[29, 30] In addition, in species from *Schistosoma* genus*,* such as *S. mansoni* and *S. japonicum,* also were identified these regulatory molecules [10, 31, 32], showing that there have been an evolutionary conservation of these molecules.

Stroehlein et al. (2018) described mature and precursor miRNAs in *S. haematobium* genome data, however, they did not mention the identification, characterization and expression of the miRNA pathway genes in the organism under study, as observed in our results. In addition, we were able to identify conserved and novel miRNAs, being 149 mature miRNAs and 131 miRNA precursors. Stroehlein and colleagues found 36 conserved miRNAs and 53 new miRNAs, while we identified 41 conserved miRNAs in the *Schistosoma* genus and 108 conserved miRNAs in others animal species. Of all mature miRNAs identified in both studies, only 25 mature miRNAs were found in both studies. 124 novel conserved mature miRNAs were found in this study comparing to Stroehlein and colleagues (2018) work. We also have validated the presence of the mature *S. haematobium* miRNAs using public smallRNA-seq libraries of male and female *S. haematobium* parasites.[32]

In miRNA processing and maturation, the proteins ARGONAUTE, DICER and DROSHA play a several key roles. In the nucleus, DROSHA complex protein is responsible for the first step in this pathway. The pri-miRNA is the product of the transcription characterized mainly by the formation of a stem-loop. This structure is targeted by DROSHA complex, that acting by the cleavage generate the pre-miRNAs.[33] Protein DICER cleaves the pre-miRNAs removing the loop from the structure forming a miRNA duplex. In the RISC complex, DICER protein guides the miRNA duplex to ARGONAUTE proteins which one of the mature miRNA in the duplex target the target gene. A lot of others proteins are part of the RISC complex such as Fmr1, Tsn, VIG, among others.[34]

The family of ARGONAUTE proteins has two important subfamilies, AGO and PIWI. Both subfamilies play important roles in noncoding RNA pathways, being the AGO proteins the main protein of the RISC complex in the microRNA and small interfering RNA (siRNA) pathways, while PIWI proteins is responsible for specific RISC complex in PIWI-interecting RNAs (piRNA) pathway.[35] This both

ARGONAUTE subfamilies have shown two highly conserved domains, PIWI and PAZ domains. The PAZ domain has been presented at the N-terminal of the protein, while the C-terminal region has been composed by PIWI domain. The positions of theses domains are strategic, since they have the ability to position the small RNA in its target gene.[36, 37] The PIWI domain, in particular, has a catalytic site responsible for cleaving target messenger RNA (mRNA) of the miRNA. This active site has been composed by three amino acid residues: DDH (aspartate, aspartate and histidine) or DDD (three aspartates).[36]

All of these aspects in our analysis had a great importance. The putative ARGONAUTE genes found in *S. haematobium* Egypt showed the conserved domains, PAZ and PIWI. The phylogenetic tree showed two distinct clades. One clade showed only AGO orthologue proteins including sht_Ago_MS3_08447 and sht_Ago_MS3_0114 suggesting that these sequences are ARGONAUTE proteins. Furthermore, the catalytic site was identified in the PIWI domain of the *S. haematobium* Egypt ARGONAUTE proteins (DDH) corroborating with PIWI domain catalytic site reported by the literature. These proteins are considered one of the most important proteins involved in the miRNAs pathway, because they are catalytic component of RISC complex and help in the high silencing capacity of the miRNAs.[38, 39]

All conserved domains described for the DICER and DROSHA proteins were found in the analyses of this work, where DROSHA showed the same conserved domains reported by others studies and DICER presented, besides the mentioned domains for this protein, one Dicer Dimer domain. It is important to emphasize that this analysis was possible once we used the new gene prediction beyond the predicted proteome from SchistoDB. We were able to improve the prediction of putative protein *S. haematobium* DROSHA. The presence of these domains found in *S. haematobium* Egypt DICER and DROSHA confirm that these proteins are ortholog of DICER and DROSHA. The DICER protein contains three main conserved domains, one PAZ domain and two domains called RNase III.[15, 39] In *S. mansoni,* in the sequences identified as DROSHA, were found three conserved domains: two RNase III and one DSRM domain.[15]

In addition, the analyses performed to identify the active site of two RNase III domains of DICER showed the distribution of following amino acids: glutamic

acid (E), aspartate (D), aspartate (D) and glutamic acid (E), forming the site EDDE also present in *S. mansoni*.[15] These findings found in DICER, DROSHA and AGO-like proteins of *S. haematobium* corroborate with the literature in domain distribution, conservation of active site and phylogenetic distribution confirming Thais prediction within *S. haematobium* data.

In the expression analysis using RNAseq data – SRR6655495, SRR6655497, SRR6655493 – the *S. haematobium* transcripts of ARGONAUTE, DROSHA and DICER showed in general low expression level in all three stages of development analyzed. The highest expression way round for the VIG gene explained by the importance of this gene not only in the RISC complex of miRNA pathway but also in other mechanisms in the parasite such as the formation and maintenance of heterochromatin.[40]

24 mature miRNA sequences identified corroborated with Stroehlein et al. (2018) study such as bantam, let-7, miR-124 and others. Some studies involving *S. japonicum* were performed to identify miRNAs based on computational and experimental analysis. Xue et al. (2008) described 5 novel miRNAs while Huang et al. (2009) found 176 mature miRNAs using computational analyses.[41] In *S. mansoni* 67 mature miRNAs and 42 precursor miRNAs were identified by Gomes et al. (2011) and 11 mature miRNAs were confirmed by experimental analyses by Simões et al. (2011).[42] A comparison between *S. mansoni* and *S. haematobium* Egypt data showed that among the conserved miRNAs found in *S. mansoni*, only five of them were not identified in *S. haematobium* Egypt genome data in our study.

Most of the miRNA precursor genes was found in the intergenic regions of the *S. haematobium* Egypt genome (Table S2) corroborating with most animal species. We found 15 miRNAs in clusters. MiRNAs distributed in clusters has also been showed in other organisms such as in *S. japonicum*, *S. mansoni* and *B. glabrata.*[10, 41, 43, 44, 45] The miRNA cluster gene mir-71/2a-1/2b/2e found in this work (Figure S2) has been reported in other organisms such as *S. mansoni*.[10] The miRNA antiparallel clusters had been also occasionally found in other animals genomes deposited in miRBase version 22 (http://www.mirbase.org/), such as smp-miR-124b and smp-miR-124a from *S. mansoni*, mmu-miR-124-2 and mmu-

miR-124b from *Mus musculus*, and oni-miR-124a-3 and oni-miR-124b-1 from *Oreochromis niloticus,* corroborating to our results (Table S2).

The pre-miRNAs sequences of *S. haematobium* Egypt displayed a Minimal Energy Free (MFE) with a mean of -25.3 kcal/mol, with values between -48.5 and -18.5 kcal/mol, and, considering the structural and thermodynamic characteristics already reported for miRNAs, a precursor miRNA molecule is stable and can generate mature miRNA having a value of the MFE of -20 kcal/mol. Besides that, this data corroborating with the values found in others animals studies, beyond corresponding to the values used for the orthologs *S. mansoni* and *S. japonicum*.[10, 42] The pre-miRNA size (~70nt) of *S. haematobium* miRNAs corroborated to orthologous size, indicate a high probability that these sequences are real pre-miRNA sequences.

In addition, the guanine-cytosine (GC) content found in the results of this work showed a distribution between 21.28% and 45.94% of GC content, but the majority of the sequences presented a percentage greater than 25%. This is one of the main parameters for pre-miRNAs identification and the presence of these nucleotides is very important for the stability of pre-miRNA secondary structure. In animals, evaluation value of this parameter should be found between 20% and 55%. As showed, the results indicated that the sequences analysed satisfy the requirements to be considered miRNA precursors. Previous works have shown how important has been the use of these structural and thermodynamic characteristics for conserved miRNA elucidation and prediction in the genome.[10]

The statistical analyses using thermodynamic and structural characteristics of the *S. haematobium* Egypt pre-miRNAs, when comparing the genus *Schistosoma* showed no differences between the groups ($p>0.05$). Both displayed high conservation and similarity among pre-miRNAs from *S. haematobium* Egypt and species belonging to the genus *Schistosoma*. However, the results for *S. haematobium* Egypt were significantly different from results for other clades such as Ecdysozoa*,* Cnidaria and Porifera ($p<0.05$), suggesting an evolutionary conservation of the pre-miRNA characteristics within each animals clade (superphylum, phylum or genus) and a significant difference among different clades (Table S4). The studies based on specific characteristics of mature and

precursor miRNAs have been used in sequence groups in different species, from Protista to Metazoa and Plantae.[11, 46, 47, 48]

Our analyses using the libraries of small RNAs from male and female adult worms showed a validation of all 149 mature miRNAs found in the genome of *S. haematobium* Egypt (Table S5). Some conserved miRNAs such as bantam-3p, let-7-3p, miR-124-3p and miR-10-5p demonstrated a large number of reads in two libraries studied, corroborating with the results found in a previously published study[32], however, our findings refer to mature miRNAs. Other miRNAs have also identified in both studies, such as the miRNAs of the miR-2, miR-7 and miR-8 families demonstrating the importance of these molecules in both libraries, female and male adult worms.[32]

The miR-10 was found in *S. haematobium* Egypt genome containing two mature miRNAs (sht-miR-10-5p and sht-miR-10-3p), corroborating with results observed in studies with *D. melanogaster* and *S. japonicum.*[43, 49] Besides that, when compared to the pre-miR-10 sequences of *S. mansoni*, *S. haematobium* Egypt and *S. japonicum* had 100% identity in the region of their two mature miRNAs (Figure 7). Many different animal species have shown this miRNA and its presence in the HOX cluster, composed by miR-10 and HOX genes. This relationship was observed in organisms such as *S. mansoni, A. gambiae*, *Tribolium castaneum,* zebrafish and human.[10, 50] On the other hand, miR-10 was one of five miRNAs considered pathogen-specific found in rabbits infected with *S. japonicum*, which may offer a new biomarker to diagnose schistosomiasis.[51]

The results miR-8 precursor shown two mature miRNAs. Besides that, in *S. haematobium* a high conservation was observed among the species belonging to Lophotrochozoa and Ecdysozoa clades, being considered a Protostome-specific miRNA, corroborating with *S. mansoni* data.[52] This miRNA was found in several organisms, including the model organism *Drosophila* sp. that was also identified by computational analyses.[49] In another study, miR-8 was identified in two mosquito's vector: *Aedes albopictus* and *Culex quinquefasciatus*.[53] In *S. japonicum,* miR-8 also was identified and presented a greater expression in mature adult worms, but was observed with some nucleotide substitutions considered specific for *Schistosoma* sp.[43] MiR-8-3p was found 11 times more reads in the male library compared to the amount of reads found in the female

library which were 104 reads. For mature miRNA miR-8-5p, none read was found in the male library and in the female library.

The miR-2 family showed five precursors and ten mature miRNA in *S. haematobium* data. This family is specific of protostome organisms, since in the phylogenetic tree were found only organisms from Ecdysozoa and Lophotrochozoa clades, corroborating with the results shown by Gomes et al. (2013). Besides that, miR-2 family has considered one of the larger miRNA family found in *D. melanogaster* presenting eight miRNAs in the genome.[54] On the other hand, in *C. elegans*, another model organism, there is only one sequence of this family.[55] In *S. mansoni*, nine members belonging to the miR-2 family were identified and some were in the cluster with miR-71.[10] This cluster is located on a sexual chromosome in the parasite and therefore, may play a role in their sexual maturation.[44]

The sequences of miR-7 family corroborated with miRNAs found in *S. mansoni*. In addition, the secondary structures performed for miR-7b, in both studies, show a high conservation of these sequences.[52] This family is one of the most conserved miRNA families and was found in all Bilateria, including flatworms, nematodes, insects and vertebrates.[56] In *S. japonicum*, miR-7 was more expressed in male worms than in females; on the other hand, this miRNA is expressed in a specific stage of parasite life, mainly in cercariae stage. Data involving the validation of these miRNAs showed that in the small RNA library of adult male there were more reads of miR-7 compared to adult female library. The mature miRNA miR-7-5p demonstrates 25 times more reads in males library compared to females library. The miR-7 is related with different cellular processes. In *Drosophila* sp., it was reported its involvement in the formation of photoreceptor organs[57] and in a study with rat pancreas was observed that miR-7 is the miRNA most abundant in this cell type, confirming the performance flexibility of this miRNA.[58]

According to the results obtained in this work, through bioinformatics and computational analyses we were able to identify 14 key proteins involved in small RNA processing pathway. Our results showed that the miRNA pathway genes were transcriptionally active. In addition, we identified 149 mature miRNAs and 131 pre-miRNAs in the genome of this species, being highly conserved in their

sequences, corroborating with others studies involving *S. mansoni* and *S. japonicum*. The results found in this work will open up a new avenue for studying the miRNAs in the *Schistosome* biology and technologies involving the gene silencing control in this organism. In addition, will allow understanding many processes and mechanisms in their biology, since these molecules present a significant regulatory role for different mRNAs, affecting various characteristics of the organism in different stages and environmental conditions.

ACKNOWLEDGEMENTS

The authors thank the members of the Laboratory of Bioinformatics and Molecular Analysis (LBAM) - UFU for providing computational structure and for helping with the data mining and the figure/table organization.

AUTHOR'S CONTRIBUTION

M.S.G., T.C.S.C., C.B.A., L.G.P. and L.G.A.M. proposed the research. M.S.G., T.C.S.C., C.B.A., L.G.P. and L.G.A.M. designed the experiments. T.C.S.C., C.B.A., L.G.P., L.G.A.M., T.C.A. and L.R.A. prepared samples. T.C.S.C., C.B.A., L.G.P., T.C.A., G.C.S., T.H.C.R., P.E.G. and L.R.A. performed experiments. T.C.S.C., C.B.A., L.G.P. and E.R.M., wrote manuscripts and prepared figures. M.S.G. supervised the project. All authors reviewed the manuscript.

ABSTRACT

Acylsugars are allelochemicals secreted by type IV trichomes in leaves and have been associated with resistance to arthropod pests in *Solanaceae* species. In this study, the putative genes involved in the acylsugar metabolism were identified, characterized, and validated in cultivated tomato, *Solanum lycopersicum*, and wild tomato, *Solanum pennellii*. Eighty-seven putative genes were identified in *S. lycopersicum* and 77 in *S. pennellii* involved in the acylsugar pathway, including the key proteins branched-chain keto acid dehydrogenase E2 (BCKD E2), 2-isopropylmalate synthase A (IPMSA), and threonine deaminase/dehydratase (TD). The putative tomato proteins displayed conservation using conserved domain distribution and active site comparing to ortholog proteins from the acylsugar pathway. Phylogenetic analysis of the putative proteins BCKD E2, IPMSA, and TD showed that all putative tomato proteins grouped with their orthologs from the *Solanaceae* species, corroborating with the distribution of the tree of life. The BCKD E2 and the IPMSA transcripts from *S. pennellii* showed higher gene expression compared to *S. lycopersicum* transcripts, suggesting that the acylsugar pathway is more active in wild than in cultivated tomato, corroborating with the literature. Given the important role of the allelochemicals produced in *Solanaceae*, the results contribute to a better understanding of acylsugars and their processing pathways and open up opportunities to study their relationship with biotic resistance in these important species and other *Solanaceae* species.

Keywords: Acylsugar; Allelochemicals; Trichomes; *Solanum lycopersicum*; *Solanum pennellii*; Resistance to pests; bioinformatics tools.

5.1 INTRODUCTION

Tomato is one of the most important vegetable crops in the world due to its significance in the economy, in generating jobs and income, and in the large volume of labor and resources produced through its production and industrial chain (Knapp, 2002; Sato and Tabata, 2016). Currently, Brazil ranks among the 10 largest producers in the world, producing more than 4 million tons of fruit in 2019 (FAO, 2019; IBGE, 2020).

The genus *Solanum* is one of the largest among the angiosperms and contains ~1500 species (Bauchet and Causse, 2012). *Solanum lycopersicum,* the cultivated tomato, has greater prominence for being one of the most consumed and studied fruits (Baichoo and Jaufeerally-Fakim, 2016; Karkute et al., 2018; Kim et al., 2011; Perez-Fons et al., 2014). Besides being a nutritious food, tomato, it has many interesting characteristics such as a fleshy fruit with compound leaves, multicellular and glandular trichomes, among several other important characteristics that other model plants (e.g., *Arabidopsis thaliana*) do not have. These traits make tomato a model plant for species that exhibit these characteristics (Bedinger et al., 2011; Campos et al., 2010; Gapper et al., 2013; Giovannoni, 2004; Kobayashi et al., 2014).

In general, commercial *S. lycopersicum* tomato plants are susceptible to pest attack and more than 200 diseases caused by different types of pathogens, including viruses, bacteria, fungi, and nematodes (Bai and Lindhout, 2007; Haapalainen, 2014; Lukyanenko, 1991; Mcgovern, 2015; Nowicki et al., 2012). Their control is mainly achieved by the use of insecticides and acaricides, which, in addition to high costs, involves intensive application, which has a negative impact on the environment through environmental pollution and ecological imbalance (elimination of natural enemies) (Ercolano et al., 2012).

Many wild tomato species produce several allelochemicals that have been associated with resistance to various arthropod pests (Bleeker et al., 2011; J. A. Freitas et al., 2002; Gonçalves et al., 1998; Gonçalves Neto et al., 2010; Maluf et al., 1997; Oliveira et al., 2009). However, these wild species have not shown immediate commercial value (Silva, 2009; Williams et al., 1980). *Solanum pennellii* is a wild tomato species relatively distant from the domesticated species *S.*

lycopersicum, with an estimated divergence time of 2.7 million years (Kamenetzky et al., 2010). They have been widely used in breeding programs to construct populations and lines due to their tolerance to stress, resistance to pests, and unusual morphology (A. Bolger et al., 2014; Fernandez-Pozo et al., 2015). *S. pennellii* lines, including LA-716, have a high level of resistance to whitefly, aphids, mites, Lepidoptera (such as the tomato moth), and other relevant tomato pests of importance around the world (Gentile et al., 1969, 1968; Goffreda et al., 1989).

Different allelochemicals found in *Solanum* species have been associated with resistance to pests such as 2-tridecanone, a methyl ketone found in *S. habrochaites* var. *glabratum* (Gonçalves et al., 1998; Maluf et al., 1997), the sesquiterpenes found in *S. lycopersicum* and *S. habrochaites* (Bleeker et al., 2011; Eigenbrode et al., 1994), and the acylsugars found in *S. pennellii* (J. A. De Freitas et al., 2002; Goffreda et al., 1989). Thus, the selection for high levels of these allelochemicals could be an efficient indirect screening technique to identify lines resistant to pests such as the tomato moth (Gonçalves Neto et al., 2010; Oliveira et al., 2009; Resende et al., 2006), whitefly (J. A. De Freitas et al., 2002) and *Tetranychus* spp. mites (Maluf et al., 2001).

The broad-spectrum disease resistance in wild tomato is attributed to the presence of glandular trichomes that occupy the plant surface, mainly type IV trichomes in leaves, and the allelochemicals they secrete (Gentile et al., 1968; Goffreda et al., 1989). Acylsugars are fatty acid esters with 4 to 12 carbon atoms that contain glucose or sucrose and constitute approximately 90% of the total of allelochemicals secreted by type IV trichomes. These allelochemicals may also play an important role in the resistance to tomato pests because of their sticky texture, acting as an insect trap by reducing larval development and impairing feeding and oviposition of the arthropods (Gomes et al., 2017; Hawthorne et al., 1992; Juvik et al., 1982; Kim et al., 2012).

The acylsugars found in the *Solanaceae* family is organized according to the sugar moiety, such as glucose or sucrose, the fatty acid moiety, and the acylation arrangement (Shapiro et al., 1994). The variety of acylsugar molecule structures is related to the diversity of biosynthetic pathways (Goffreda et al., 1990; Shapiro et al., 1994).

Several studies have shown the contribution of many proteins to the acylsugar metabolism in plants (Hoeven et al., 2000; Kandra et al., 1990; Kim et al., 2012; Kroumova and Wagner, 2003; Leckie and Halitschke, 2014; McDowell et al., 2011; Ning et al., 2015; Schilmiller et al., 2015; Slocombe et al., 2008; Walters and Steffens, 1990). Among all proteins involved in the acylsugar metabolism, thosefrom BCKD E2, IPMSA, and TD families have been considered the key proteins of the acylsugar pathway (Kandra et al., 1990; Ning et al., 2015; Slocombe et al., 2008; Walters and Steffens, 1990).

The multi-enzymatic complex BCKD is composed of three subunits, 2-oxo acid dehydrogenase (E1), dihydrolipoyl acyltransferase (E2), and dihydrolipoamide dehydrogenase (E3), and plays a key role in redox regulation. E2, the central component of the complex, catalyzes the transfer of the acyl-CoA group from E1 to E3 via the reductive acetylation of a lipoyl group that is covalently attached to a lysine residue (CDD, 2016). BCKD catalyzes the conversion of the branched chain keto acids into the branched chain acyl-CoAs with the loss of one carbon in a decarboxylation process (Slocombe et al., 2008). In plants, BCKD is involved in the first step of branched chain amino acid (BCAA) catabolism and plays an important role in the synthesis of branched chain fatty acids (BCFA) (Mooney et al., 2002; Slocombe et al., 2008; Taylor et al., 2004). The enzyme TD is responsible for catalyzing the direct deamination of the alpha-amino group of threonine into $NH4^+$ in amino acid degradation, with pyridoxal phosphate (PLP) as the prosthetic group (CDD, 2016). Besides, TD is essential for the supply of ketoacid precursors (2-keto-3-methyl valerate and 2-ketoisovalerate) and precursors for acylsugar production and is involved in the first step of isoleucine and BCFA synthesis in trichomes (Slocombe et al., 2008). The enzyme IPMS is responsible for catalyzing the aldol type condensation of acetyl-CoA reductase and 2-oxoisovalerate, producing 2-isopropylmalate and CoA, which is the first step in leucine biosynthesis (CDD, 2016; Hoeven et al., 2000). In addition, the variation of 2-methylpropanoic acid (iC4) and 3-methylbutanoic acid (iC5) acyl chain in S. pennellii accessions is influenced by the variation in the activity of a set of truncated IPMS enzymes (Ning et al., 2015). Ning et al. (2015) observed that *S. lycopersicum* expresses an *IPMS* gene (Solyc08g014230 - chromosome 8) in the apical cells of type I/IV trichomes, which encodes a functional protein with 160

amino acids less at the end in the C-terminal region than the *IPMS* gene (Solyc06g053400) expressed from chromosome 6. Although the protein is active at *in vitro* conditions, it is insensitive to leucine-binding mediated inhibition in the regulatory domain as it has been described in Arabidopsis (Kraker and Gershenzon, 2011) and microorganisms (Carvalho et al., 2005; Koon et al., 2004; Ning et al., 2015). In contrast, an *IPMS* gene (Sopen08g005140) on chromosome 8 of *S. pennellii* encodes a non-functional truncated IPMS protein with a major deletion in the C-terminal region (51 aa.). The deletion found in *S. pennellii* means that there is no allosteric regulation by leucine binding, with large amounts of methylpropanoic acid accumulating for acylsugar synthesis instead (Ning et al., 2015). Taking into consideration these previous studies and the importance of these allelochemicals in mediating the resistance to tomato pests, a study that analyzes and characterizes the genes involved in the acylsugar metabolism supports a better understanding of the natural defense mechanisms in different *Solanaceae* species for advances in traditional breeding and the genetic manipulation of important commercial species.

Considering the importance of tomato crops and the rapid growth in agrochemical use in crops, a better understanding of the biology of the tomato is necessary for selecting markers associated with important characteristics in its response to biotic and abiotic stresses. The release of the *S. lycopersicum* (Sato et al., 2012) and *S. pennellii* genomes (A. Bolger et al., 2014) represented a great advance in the biological study of these species and deepened the annotation and identification studies of several genes. Therefore, identifying and characterizing the genes related to acylsugar pathway in *S. lycopersicum* and *S. pennellii* may help to understand the involvement of those genes in resistance to arthropods, which occurs mainly via acylsugar production. Thus, our study aimed to identify, characterize, and validate genes involved in the acylsugar metabolism in *S. lycopersicum* and *S. pennellii* genomes.

5.2 MATERIALS AND METHODS

5.2.1 Identification and characterization of putative genes involved in acylsugar metabolism in *S. lycopersicum* and *S. pennellii*

Based on literature, the genes involved in the acylsugar metabolism from model plant species (*A. thaliana*) and other species (*Solanum tuberosum, Glycine max, etc*) were searched in plant databases and retrieved as a protein FASTA file (Figure 1). These protein sequences were used as queries to search putative *S. lycopersicum* and *S. pennellii* proteins involved in the acylsugar pathway using the Blastp tool (Mcginnis and Madden, 2004). The Sol Genomics Network 2019 for both tomato species was used as a database to search the putative tomato proteins (Fernandez-Pozo et al., 2015). Other ortholog proteins from model plant species and other plants, that have been considered evolutionarily close and distant from tomato species, were retrieved using putative tomato sequences as queries and NCBI reference protein databases (RefSeq protein database 91) of the respective plant (*S. tuberosum*, *Capsicum annuum, Nicotiana sylvestris, Nicotiana tomentosiformis, Nicotiana tabacum, Glycine max, Theobroma cacao, Prunus mume, Cucumis melo, Vitis vinifera, Citrus sinensis, Nelumbo nucifera, Brassica napus, A. thaliana, Arabidopsis lyrata, Cucumis sativus, Vigna angularis, Vigna radiata, Nicotiana attenuate*, *Camelina sativa, Malus domestica, Cicer arietinum, Phaseolus vulgaris and Beta vulgaris*) (Leary et al., 2016). These protein sequences were retrieved as FASTA files and used for further analyses such as observation of sequence-structure conservation, presence of conserved domains and active sites, and phylogenetic analyses.

5.2.2 Alignment and phylogenetic analyses

Multiple Sequence Alignment (MSA) of the putative tomato proteins involved in the acylsugar pathway and their orthologs were performed by ClustalX 2.1 (Larkin et al., 2007). Conserved domains were identified and characterized using the Protein Family Database (Pfam) (El-gebali et al., 2019) and Conserved Domains Database (CDD) (Marchler-Bauer et al., 2015). Phylogenetic analysis was performed based on the putative tomato proteins and their ortholog proteins by the use of the MEGA 5.2 program using the Neighbor-joining method (Saitou and Nei, 1987; Tamura et al., 2011). A consensus tree was obtained through the Neighbor-joining (NJ) method using “2000 bootstraps”. The evolutionary distance was calculated using the JTT model (Jones et al., 1992).

5.2.3 Expression of acylsugar pathway genes in tomato RNA-seq libraries

Paired-end reads from leaves of both wild (*S. pennellii*) and cultivated (*S. lycopersicum*) tomato were retrieved from the Sequence Read Archive (SRA) under accessions numbers SRR786556, SRR786557, SRR786570, SRR786571, SRR786524, SRR786525, SRR786540, SRR786541, and SRR786542 (Dai et al., 2017).

The quality of the libraries was evaluated using the FastQC software (Kroll et al., 2014). Adapters were identified using the Minion tool from the Kraken suit for quality control of high-throughput sequence data (Davis et al., 2013), and removed using Trimmomatic (A. M. Bolger et al., 2014). Reads with a quality score below 20 and length below 35 bp were also removed using Trimmomatic. After the quality control, the library reads of *S. lycopersicum* (SRR786524, SRR786525 SRR786540, SRR786541 and SRR786542) and *S. pennellii* (SRR786556, SRR786557, SRR786570 and SRR786571) were used as input to the STAR mapper tool (version 2.5.3a) (Dobin et al., 2013) with the default parameters (Fernandez-Pozo et al., 2015). The libraries were then sorted by query name using Picard tools (version 2.18.0), and for each of them, raw read counts were obtained using the python script HTSeq-count (version 0.7.2) (Anders et al., 2015).

We searched for differentially expressed (DE) genes between leaf libraries of both species by contrasting the normalized number of counted reads aligned to the exons of genes in the *S. lycopersicum* genome. The comparisons were carried out with the Bioconductor package edgeR in the statistical environment R (Huber et al., 2015; Robinson et al., 2009). The Benjamini and Hochberg's false-discovery rate (FDR) below 0.05 and minimum fold-change of two were the parameters used to consider a gene DE (Benjamini and Hochberg, 1995).

5.2.4 Real-time PCR expression of the acylsugar pathway putative genes in *S. lycopersicum* and *S. pennellii*

The plant material was collected at the vegetable experimental station of HortiAgro Sementes SA. Two different lines were used to analyze the expression of the putative genes involved in the acylsugar processing. These lines are derived from *S. lycopersicum* and S. *pennellii*: LA-716 (*S. pennellii* wild strain with high acylsugars) and TOM-687 (pre-commercial strain of *S. lycopersicum*).

For RNA extraction, leaf trichomes of the two *S. lycopersicum* and *S. pennellii* lines were collected at three different times, under the same environmental conditions for expression analysis: 30, 60, and 90 days after planting to analyze the vegetative growth, flowering, and fruiting, respectively. The samples were immediately frozen in liquid nitrogen and stored at -80°C. The Concert ™ Plant RNA Reagent Kit (Invitrogen) was used following the manufacturer's recommendations. The samples were treated with the Turbo DNA-free Kit (Ambion) to eliminate residual DNA contamination. RNA integrity was checked on a 0.8% agarose gel. Samples were quantified in a spectrophotometer (Nanodrop® Spectrophotometer ND-1000) at A_{260}. Samples that showed a high degree of integrity and purity (OD260/OD280 = 1.8 a 2.0) were used for cDNA synthesis with the High-Capacity cDNA Reverse Transcription Kit (Applied Biosystems). After cDNA synthesis, the samples were stored in a -20°C freezer until use.

The primers for real-time PCR of the putative tomato genes involved in the acylsugar pathway and reference genes were designed using the Primer Express v2.0 program (Applied Biosystems) (Supplementary Table S1). The gene expression analysis was performed in an ABI PRISM 7500 Real-Time PCR system (Applied Biosystems) using the SYBR Green qPCR method. The cycling parameters were 2 min at 50°C, 10 min at 95°C, followed by 40 cycles of 15 s at 95°C, 1 min at 60°C, and 15 s at 95°C. Data were collected and stored in the 7500 Fast Software program (Version 2.1). For each reaction, 80 ng of cDNA, 1.5 µM of each primer, and 5.0 µL of Master Mix SYBR green UDG with ROX (Invitrogen) were used in a final volume of 10.0 µL/sample. The reference genes *eukaryotic elongation factor 1* (*eEF-1*) and *glyceraldehyde-3- phosphate dehydrogenase* (*GAPDH*) were used as endogenous genes. The method used was the comparative C_T (Pfaffl, 2001). The normalization was calculated by the equation $\Delta C_T = C_T$ (target gene) - C_T (endogenous control), and the calibration was determined by the formula $\Delta\Delta C_T = \Delta C_T$ (sample) - ΔC_T (calibrator). Relative quantification was obtained by the formula $2^{-\Delta\Delta C_T}$.

For the statistical comparisons among the expressions of the three times of each gene analyzed, a basic descriptive analysis was performed followed by non-parametric tests (Wilcoxon-Mann-Whitney). Median values were used to perform

the statistical comparisons (Moses, 2005). Statistical significance was set at $p<0.05$.

5.3 RESULTS

5.3.1 *In silico* analysis of *S. lycopersicum* and *S. pennellii* acylsugar pathway genes

Initially, we conducted a review in the literature searching for genes involved in the acylsugar metabolism of the model plant species and other plant species (Table 1). Subsequently, these genes were compared with *the S. lycopersicum* and *S. pennellii* sequence databases using the BLASTp tool. Eighty-seven putative proteins involved in the acylsugar processing pathway were identified in the *S. lycopersicum* database and 77 in the *S. pennellii* database (Supplementary Table S2).

Our analysis revealed that the components of this pathway were highly conserved at the amino acid level in *S. lycopersicum* and *S. pennellii.* Supplementary Table S3 shows the conserved domains characterized in all putative proteins involved in the acylsugar pathway. Among all putative proteins identified, the putative protein families BCKD E2, IPMSA, and TD were considered key proteins in the processing machinery of acylsugars according to previous studies and were used for further analysis (Kandra et al., 1990; Ning et al., 2015; Slocombe et al., 2008; Walters and Steffens, 1990). The distribution of the protein domains (Supplementary Figure S1 and Supplementary Table S3), the position of the amino acids from active sites (Figure 2), and the phylogenetic distribution of the putative tomato proteins BCKD E2, IPMSA and TD (Figure 3) were conserved compared to the reference ortholog proteins from other plant species.

5.3.2 BCKD E2 proteins

One putative BCKD E2 protein was found in *S. lycopersicum* (Solyc01g066520) and one in *S. pennellii* (Sopen01g028100) (Supplementary Table S2). The proteins Solyc01g066520 and Sopen01g028100 displayed the domains Biotin_lipoyl, E3_binding, and 2-oxoacid_dh at positions 90-163, 206-240, 272-502 and 90-163, 206-240, 272-502, respectively (Supplementary Figure

S1A and Supplementary Table S3). The Biotin_lipoyl conserved domain is one of the main domains contained in the BCKD E2 proteins. It was also shown that the active sites contained the important catalytic residue K (lysine) in a specific and conserved position (Figure 2A). The catalytic residues K of the BCKD E2 proteins from *S. lycopersicum* and *S. pennellii* were found at positions Lys130 on both proteins. The conserved domains and active sites found in Sly (*S. lycopersicum*)/Spe (*S. pennellii*) BCKD E2 showed high conservation compared to the BCKD E2 proteins in other plant species, such as *S. tuberosum, N. tabacum, T. cacao, A. thaliana*, *G. max,* and *V. vinifera*.

The phylogenetic distribution of BCKD E2 proteins was performed using amino acid sequences (Figure 3A). The phylogenetic analysis of the Solyc01g066520 and Sopen01g028100 proteins showed that these putative proteins were distributed in the phylogenetic tree closest to their respective ortholog proteins from other plant species. The phylogenetic tree was divided into clades of 9 distinct families: *Solanaceae, Fabaceae, Malvaceae, Rosaceae, Cucurbitaceae, Vitaceae, Rutaceae, Nelumbonaceae,* and *Brassicaceae*.

5.3.3 IPMSA proteins

Another important catalytic component of the acylsugar processing pathway in plants are the IPMSA proteins. Three putative proteins were identified in *S. lycopersicum* (Solyc08g014240, Solyc08g014230 and Solyc08g014130), and four putative proteins were identified in *S. pennellii* (Sopen08g005060, Sopen08g005140, Sopen10g006110 and Sopen08g005150) (Supplementary Table S2).

The Solyc08g014130.2.1 and Sopen08g005060 proteins showed the HMGL-like and LeuA_imer conserved domains in their structures. The HMGL-like domain was shown at positions 72-352 and 51-331, and the LeuA_imer domain was shown at positions 451-596 and 426-571 in the Solyc08g014130.2.1 and Sopen08g005060 proteins, respectively. The Solyc08g014240, Solyc08g014230, Sopen08g005140, Sopen10g006110, Sopen08g005150 proteins showed only the HMGL-like domain at positions 15-295, 15-331, 51-331, 51-331 and 15-295, respectively (Supplementary Figure S1B and Supplementary Table S3).

The HMGL-like domains in both tomato species showed the same catalytic residues, aspartate (D), arginine (R) and glutamate (E), and these of catalytic triad (DRE domain), corroborating with IPMSA proteins from other plant species (Figure 2B). These residues were found in the HMGL-like domains of the *S. lycopersicum* proteins Solyc08g014240 (Asp25-Arg94-Glu161), Solyc08g014230 (Asp61-Arg130-Glu197), and Solyc08g014130 (Asp82-Arg151-Glu218) and the *S. pennellii* proteins Sopen08g005060 (Asp57-Arg126-Glu193), Sopen08g005140 (Asp61-Arg130-Glu197), Sopen10g006110 (Asp61-Arg130-Glu197), and Sopen08g005150 (Asp25-Arg94-Glu1610).

To determine the evolutionary relationship among the putative IPMSA proteins of *S. lycopersicum* and *S. pennellii* and their orthologs, a phylogenetic analysis was performed to confirm the phylogenetic distribution of these putative proteins among their orthologs (Figure 3B). The proteins were grouped into 6 family clades (*Malvaceae, Brassicaceae, Cucurbitaceae, Fabaceae, Vitaceae,* and *Solanaceae*).

5.3.4 TD proteins

Three putative TD proteins were identified in *S. lycopersicum* (Solyc09g008670, Solyc10g083760, and Solyc10g083540) and three in *S. pennellii* (Sopen09g003470, Sopen10g033010, and Sopen10g033220) (Supplementary Table S2). The putative proteins Solyc09g008670, Solyc10g083760, Solyc10g083540, Sopen09g003470, Sopen10g033010, and Sopen10g033220 showed the PALP domain at positions 106-397, 117-409, 103-395, 68-359, 103-395, and 117-409, respectively. The same proteins showed the Thr_dehydrat_C I domain at positions 410-500, 422-512, 408-498, 372-462, and 408-498 and the Thr_dehydrat_C II domain at positions 504-593, 516-605, 503-591, 466-555, 503-591, and 422-512, respectively (Supplementary Figure S1C and Supplementary Table S3).

Almost all putative TD proteins from *S. lycopersicum* (Solyc09g008670 - Lys143, Solyc10g083760 - Lys154 and Solyc10g083540 - Lys140) and *S. pennellii* (Sopen09g003470 - Lys105, Sopen10g033010 - Lys140 and Sopen10g033220 - Lys154) showed at the PALP domain a catalytic K (lysine) residue (Figure 2C).

The phylogenetic analysis of the *S. lycopersicum* and *S. pennellii* TD proteins showed that they were distributed in the phylogenetic tree closest to their respective ortholog proteins of other plant species (Figure 3C). The phylogenetic tree showed 8 distinct clades distributed in 8 plant families: *Solanaceae, Vitaceae, Amaranthaceae, Cucurbitaceae, Malvaceae, Rosaceae, Fabaceae,* and *Brassicaceae*.

5.3.5 Transcriptomic changes in tomato leaves RNA-seq-based

To confirm the expression of the acylsugar pathway components, RNA-seq data of *S. lycopersicum* and *S. pennellii* were searched on the publicly available database Sequence Read Archive (SRA) (Dai et al., 2017). The results confirmed the expression of genes identified in the leaves of the two species (Figure 4). Eighteen genes (*Acetyl-CoA synthase, AT2, 3 AT3, 2 AKR, BCAT, BCKD E1a, 3 BCKD E2, IPDS, IPMD, IPMSA, Isovaleryl-CoA dehydrogenase 1, KAS II,* and *KAS III*) involved in the acylsugar processing pathway were found to be differentially expressed (DE) in *S. lycopersicum* and *S. pennellii* leaf samples.

Among 18 DE genes, 12 were up-regulated (*AT2,* three *AT3, AKR, BCAT,* two *BCKD E1a, BCKD E2, IPMSA, KAS II,* and *KAS III*) and 6 were down-regulated (*Acetyl-CoA synthase*, *AKR, BCKD E1a, IPDS, IPMD, Isovaleryl-CoA dehydrogenase 1*) in *S. pennellii*. Considering the relative expression in LogFC, *AT2* was the most expressed gene in *S. pennellii* leaves. Then, the *BCAT, AT3, IPMSA,* and *KAS III* genes showed the highest expression in the leaves of wild tomato compared to cultivated tomato. The down-regulated genes in *S. pennellii* and up-regulated in *S. lycopersicum* were *AKR, IPDS, BCKD E1a, Acetyl-CoA synthase,* and *Isovaleryl-CoA dehydrogenase 1*.

5.3.6 Real-time PCR validation of the BCKD E2, IPMSA and TD transcripts involved in the acylsugar pathway in *S. pennellii* (LA-716) and *S. lycopersicum* (TOM-687)

The leaf trichome samples from *S. pennellii* and *S. lycopersicum* were collected at three different times: 30, 60, and 90 days after planting to analyze the vegetative growth, flowering and fruiting, respectively. The real-time PCR analysis displayed different expression levels of the BCKD E2, IPMSA and TD transcripts.

The BCKD E2 transcripts had a different expression among the tomato species. *S. pennellii* BCKD E2 transcripts showed higher expression compared to *S. lycopersicum* BCKD E2 transcripts (p=0.000) (Figure 5A and Supplementary Table S4). Regarding the different times (30, 60, and 90 days), *S. pennellii* BCKD E2 transcripts showed higher expression (p<0.05) compared to *S. lycopersicum* BCKD E2 transcripts (Figure 5B and Supplementary Table S5).

Similar to BCKD E2, the IPMSA transcript showed higher expression in *S. pennellii* than in *S. lycopersicum* (p=0.000) (Figure 5C, 5D, and Supplementary Table S4). Regarding the three times studied, just as with the *BCKD E2* gene, the *S. pennellii* IPMSA transcript showed higher expression (p<0.05) at the three times (30, 60, and 90 days) than the *S. lycopersicum* IPMSA transcript at the three times. In addition, *S. pennellii* at 90 days showed higher expression than at 30 days (p=0.000), but showed lower expression than at 60 days (p=0.004). The *IPMSA* gene was more expressed at 60 days (p=0.004) compared to 90 days in *S. lycopersicum* (Figure 5D and Supplementary Table S6).

In contrast to BCKD E2 and IPMSA, the TD transcripts in the first analysis showed no different expression (p>0.05) between the two tomato species (Figure 5E and Supplementary Table S4). However, regarding the different times, it was observed a higher expression of the two tomato species at 60 days (flowering stage) compared to 30 days (vegetative growth stage), and 90 days (fruit set stage). Besides, the *S. pennellii TD* genes at the time of 60 days were more expressed than at 30 and 60 days (Figure 5F and Supplementary Table S7).

5.4 DISCUSSION

To better understand the biology, evolution, and domestication of the tomato regarding the acylsugars and the genes of their metabolic pathway, *in silico* and *in vitro* analysis were performed in cultivated tomato *S. lycopersicum* and the wild tomato *S. pennellii*. Overall, our results suggest that the acylsugar pathway genes are conserved in both tomato species, demonstrating a similar evolutionary pattern. However, a greater number of genes were found in cultivated tomato and higher levels of expression of these genes were found in the wild tomato. These findings suggest a possible gain of genes along the evolution and

domestication, together with a decrease in the expression of those genes due to the presence of isoforms, thus sharing or lacking their functions.

We identified 87 and 77 putative proteins involved in the acylsugar processing pathway in *S. lycopersicum* and *S. pennellii*, respectively (Supplementary Table S2). The analysis revealed that the components of this pathway in both tomato species were highly conserved at the amino acid level showing conserved domains (Supplementary Table S3 and Supplementary Figure S1), conserved amino acid residues in catalytic sites (Figure 2), and a phylogenetic distribution similar to the tree of life (Figure 3). These results were observed in the three protein families BCKD E2, IPMSA, and TD in both tomato species. These proteins play a key role in the acylsugar pathway according to other studies (Kandra et al., 1990; Ning et al., 2015; Slocombe et al., 2008; Walters and Steffens, 1990). However, the complete pathway of acylsugar in plants has not been described yet in the literature (Kandra et al., 1990; Ning et al., 2015; Slocombe et al., 2008; Walters and Steffens, 1990; Xu et al., 2013).

The genes BCKD E2, IPMSA, and TD perform important functions in the production of acylsugars. Among all proteins identified, one of the BCKD E2 family was found in both *S. lycopersicum* and *S. pennellii* genomes (Supplementary Table S2, Supplementary Figure S1A, and Supplementary Table S3). These genes have been also identified in other plant species (e.g., *Humulus lupulus* and *N. benthamiana*) (Slocombe et al., 2008; Walters and Steffens, 1990; Xu et al., 2013). The BCKD E2 protein active sites contained the important catalytic residue K (lysine) in a specific and conserved position (Figure 2A). This lysine residue is critical in the performance of these proteins because the BCKD E2 proteins catalyze the transfer of the acyl group of CoA to the reductive acetylation of a lipoyl group that is covalently attached to the lysine residue (CDD, 2016). This high conservation at the amino acid level in the active site might be directly related to the normal function of the BCKD E2 proteins in the acylsugar processing pathway in different species.

The IPMSA is another important catalytic component of the acylsugar processing pathway in plants. In *S. lycopersicum* and *S. pennellii,* three and four of these proteins were identified, respectively, and were also present in other plant species such as *N. benthamiana* (Slocombe et al., 2008). Members of the IPMS

protein family have a conserved HMGL-like triose-phosphate isomerase (TIM) domain (Supplementary Figure S1B and Supplementary Table S3). This catalytic domain contains a nucleus with a binding site at the divalent cation consisting of a conserved residue set that includes three invariant residues: one aspartate (D), one arginine (R), and one glutamate (E) (CDD, 2016), which were found in all IPMSA proteins of the two tomato species studied (Figure 2B).

In addition, four putative TD proteins were found in *S. lycopersicum* and three in *S. pennellii* (Supplementary Table S2, Supplementary Figure S1C, Figure 2C, and Supplementary Table S3). This protein family has also been found in other plants (e.g., *N. benthamiana*) (Slocombe et al., 2008). The PALP conserved domains identified in TD proteins had a catalytic K residue (Figure 2C). The members of this protein family are pyridoxal phosphate-dependent enzymes (PLP), which form an internal aldimine bond (Schiff base) for the action of the catalytic lysine residue (CDD, 2016). Thus, the high conservation of the domains and of the catalytic residues found in the Sly/Spe TD proteins suggest an important role of these proteins in plants, especially in the acylsugar pathway.

The phylogenetic analysis of the tomato proteins BCKD E2, IPMSA, and TD and their orthologs from other plant species corroborated with the distribution of species across the tree of life (Figure 3) (Stevens, 2001). These findings suggest high conservation among the members of the BCKD E2, IPMSA, and TD family in *Angiosperms*. Thus, it can be observed that the BCKD E2, IPMSA, and TD proteins of *S. lycopersicum* and *S. pennellii* are highly conserved, thus highlighting the great importance of these proteins in acylsugar processing in *Solanaceae*.

The validation of the acylsugar pathway genes in the libraries available in the SRA (Dai et al., 2017) showed the DE of 18 genes identified in *S. lycopersicum* and *S. pennellii* (Figure 4). The DE genes in the two species were *Acetyl-CoA synthase, AT2, AT3, AKR, BCAT, BCKD E1a, BCKD E2, IPDS, IPMD, IPMSA, Isovaleryl-CoA dehydrogenase 1, KAS II,* and *KAS III*. Twelve genes were up-regulated in *S. pennellii* and 6 were up-regulated in *S. lycopersicum*. The most expressed genes in *S. pennellii* leaves were *AT2, BCAT, AT3, IPMSA,* and *KAS III*. The AT3 and AT2 families belong to the BAHD class of acyltransferases and catalyze the third and fourth steps, respectively, of tetraacylsucrose biosynthesis in tomato, being required for adding the acetyl (C2) group found in the major

detectable tetra-acyl sucroses (Schilmiller et al., 2015, 2012). The BCAT family participates significantly in the leucine, isoleucine, and valine metabolism and is involved both in BCAA biosynthesis and degradation (Diebold et al., 2002). In addition, the KAS family is involved for both the branched and straight medium-chain fatty acid elongation in the trichome (Slocombe et al., 2008).

The BCKD E2 and IPMSA transcripts expressed differently between the species, with *S. pennellii* showing higher expression than *S. lycopersicum* at all three times (Figure 5A, 5B, 5C, 5D, Supplementary Tables S4, S5, and S6). However, the TD transcripts showed no different expression (p>0.05) between the different tomato species (Figure 5E and Supplementary Table S4), but had a different expression among the different times (Figure 5F and Supplementary Table S7). The 60-day plants showed higher expression of the gene in one species of tomato when compared to the 30 and 90 days of the other species, which indicates a greater production of metabolites in the flowering stage, suggesting that at this development stage the plant demands more defense against pests that may be attracted by flowers. These results show that, in the wild tomato, the BCKD E2 and IPMSA transcripts were more expressed compared to the cultivated tomato. In addition, the *TD* expression suggests that this gene plays an important role in tomato leaves, considering the high expression in both species, even though there is no DE. This suggests that *TD* gene might be important not only in acylsugar processing pathway but also in other metabolic pathways in tomato leaves.

The BCKD E2 and IPMSA proteins act on the acylsugar metabolism in the decarboxylation process in the keto acid conversion of the branched-chain acyl-CoAs and in the catalysis of the first step in leucine biosynthesis, producing 2-isopropylmalate and CoA (CDD, 2016; Hoeven et al., 2000; Slocombe et al., 2008). Therefore, this result shows a greater requirement of these genes in leaves, mainly in *S. pennellii*, suggesting an essential role in this tissue.

As these genes are important in the acylsugar synthesis in tomato trichomes, our results suggest that *S. pennellii* might display higher acylsugar production, which has been also shown in other studies (Gentile et al., 1968; Hoeven et al., 2000; Resende et al., 2002; Slocombe et al., 2008). Gentile et al. (1968) observed leaf resistance to whitefly in *S. pennellii* compared to other

tomato species. This resistance was observed by the sticky glandular exudate on the leaf surfaces, which is a death trap for the eggs laid on the leaves and for the adults moving on the leaves. These results indicate the presence of acylsugars, which offers resistance to arthropods in the tomato leaves (Gentile et al., 1968). Resende et al. (2002) confirmed the acylsugar presence on the leaf tomato surface of the genotype wild LA-716, which was also evaluated in our study (Resende et al., 2002). Resende et al. (2002), Neto (2008), and Lucini et al. (2015) found a higher acylsugar content in LA716 (63.75, 0.624, and 297.91 nmol/cm^2, respectively) compared to *S. lycopersicum* lines (28.26, 0.225, and 33.71 nmol/cm^2, respectively) using a colorimetric method (Lucini et al., 2015; Neto, 2008; Resende et al., 2002).

The *S. pennellii* lines used for the analysis (LA-716) showed higher acylsugar content compared to *S. lycopersicum* lines (TOM-687) in other studies (Lucini et al., 2015; Neiva et al., 2013; Neto, 2008; Talekar et al., 2006). Moreover, the expression of the pathway genes in *S. pennellii* was higher than the expression in *S. lycopersicum*.

Thus, our results demonstrate that the *BCKD E2* and *IPMSA* genes may surely be involved in acylsugar processing in tomatoes, especially in *S. pennellii*, which has a higher expression of these genes and higher production of these allelochemicals. In addition, the *TD* expression in the evaluated species suggests that this gene plays an important role in the tomato leaves. Our result suggests that these proteins are indeed important in the acylsugar processing in tomato leaves and may help to find new strategies to improve plant resistance to arthropod pests and to study the relationship between evolution, acylsugar synthesis, and biotic resistance in these two tomato species.

5.5 CONCLUSION

Considering the great importance of tomatoes and the high rate of application of agrochemicals, knowing the genes involved in the production of secondary metabolites that naturally protect the plant is necessary. In this way, the understanding of the possible involvement of acylsugars in resistance to arthropods and their association with markers related to important characteristics

will assist in the genetic improvement of these two tomato species seeking a response to the control of biotic stress. In this sense, bearing in mind the important role of allelochemical production in *Solanaceae*, our results contribute to a better understanding of acylsugars and their processing pathways and opens up opportunities to study their relationship with biotic resistance in these important vegetable crop species and other *Solanaceae* species.

6 RESULTADOS COMPLEMENTARES - Article: Description of acylsugar pathway, miRNA pathway and miRNA molecules in seven tomato species for submission in Molecular Genetics and Genomics Journal

6.1 The small RNAs processing and acylsugar pathway in *S. lycopersicum*, *S. pennellii, S. galapagense, S. chilense, S. peruvianum* and *S. pimpinellifolium*: analysis of conserved protein domains, active sites and phylogenetic trees

6.1.1 AGO and DCL proteins

Using a local alignment of the 42 *S. lycopersicum* and *S. pennellii* mRNA, previously identified (Cardoso et al. 2018), against the *S. galapagense, S. chilense, S. peruvianum* and *S. pimpinellifolium* genomes, as well as the presence and arrangement of conserved domains, we predicted proteins involved in the biogenesis of small RNAs (siRNAs, tasiRNAs and miRNAs) (Jones-Rhoades et al. 2006; Bologna and Voinnet 2014). Were identified 18 AGO and 10 DCL proteins in *S. galapagense*, 11 AGO and 10 DCL proteins in 1 *S. peruvianum,* 16 AGO and 8 DCL proteins in *S. chilense,* 17 AGO and 10 DCL proteins in *S. pimpinellifolium* LA1589 and 18 AGO and 10 DCL proteins in *S. pimpinellifolium* LA0480 (Supplementary Table S1).

Among the proteins involved in small RNA processing, AGO1, AGO10 and DCL1 proteins participate in the miRNA pathways. We found 2 AGO1 proteins in *S. galapagense, S. chilense* and *S. pimpinellifolium* and 1 AGO1 in *S. peruvianum.* We also found 2 AGO10 proteins and 1 DCL1 protein in each specie analysed.

We search the conserved domains of the all AGO proteins in species studied (Figure 1, Figure 2 and Supplementary Table S2). The AGO1 proteins identified in all species displayed the Gly-richAgo1, ArgoN, ArgoL1, PAZ, ArgoL2, ArgoMid and Piwi domains, except the contig:385000:1:10591:1 protein of the *S. pimpinellifolium* LA1589 that did not have Gly-richAgo1 and ArgoL1 domains, probably because it was truncated at the beginning of the sequence due to the sequencing of the genome (Figure 1 and Supplementary Table S2). Similar results were observed for the AGO10 proteins, which displayed the ArgoN, ArgoL1, PAZ,

34 ArgoL2, ArgoMid and Piwi domains, except the scaffold28885_12.6 protein of the
35 *S. galapagense* that have Gly-rich domain; and scaffold1098 and
36 contig:6745152:1:10334:1 proteins of the *S. chilense* and
37 contig:6745152:1:10334:1 *S. pimpinellifolium* LA1589 that, respectively, did not
38 showed ArgoL1 domain (Figure 2 and Supplementary Table S2).
39

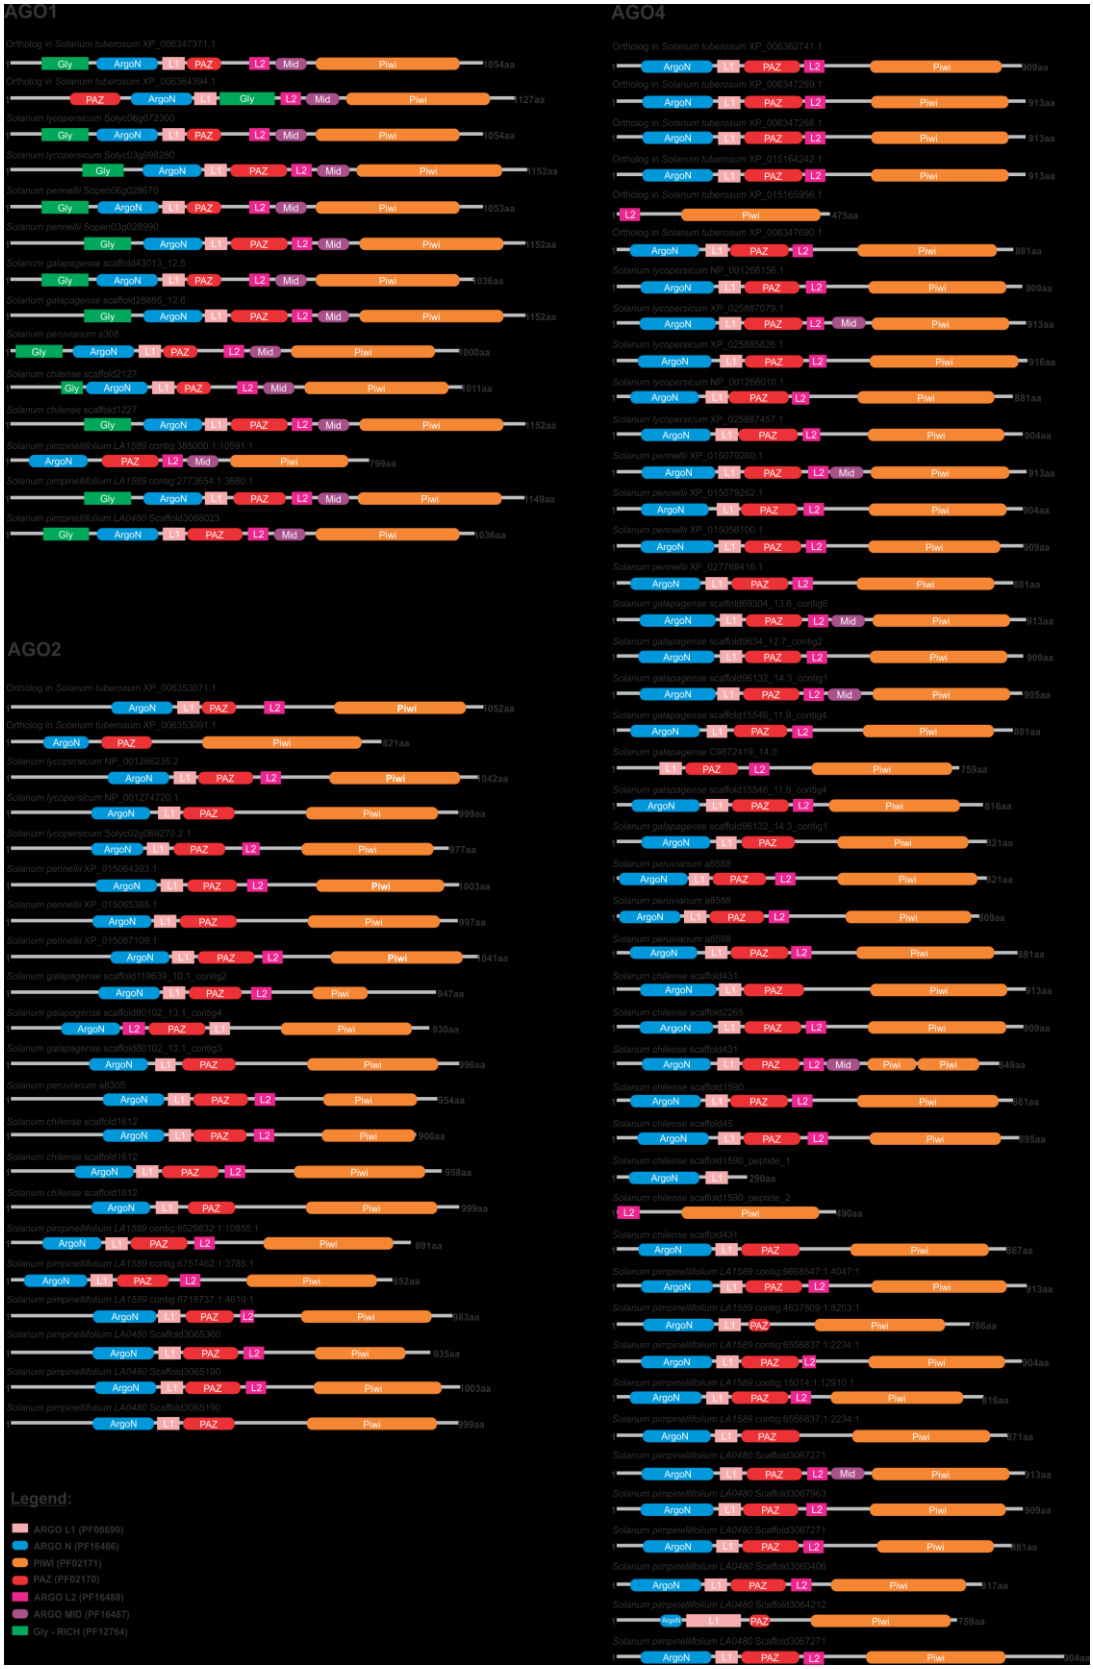

Figure 1 - Distribution of conserved domains in AGO1, AGO2 and AGO4 putative proteins of *S. lycopersicum*, *S. pennellii, S. galapagense, S. chilense, S. peruvianum*, *S. pimpinellifolium* LA0480, *S. pimpinellifolium* LA1589 and their ortholog in *S. tuberosum.*

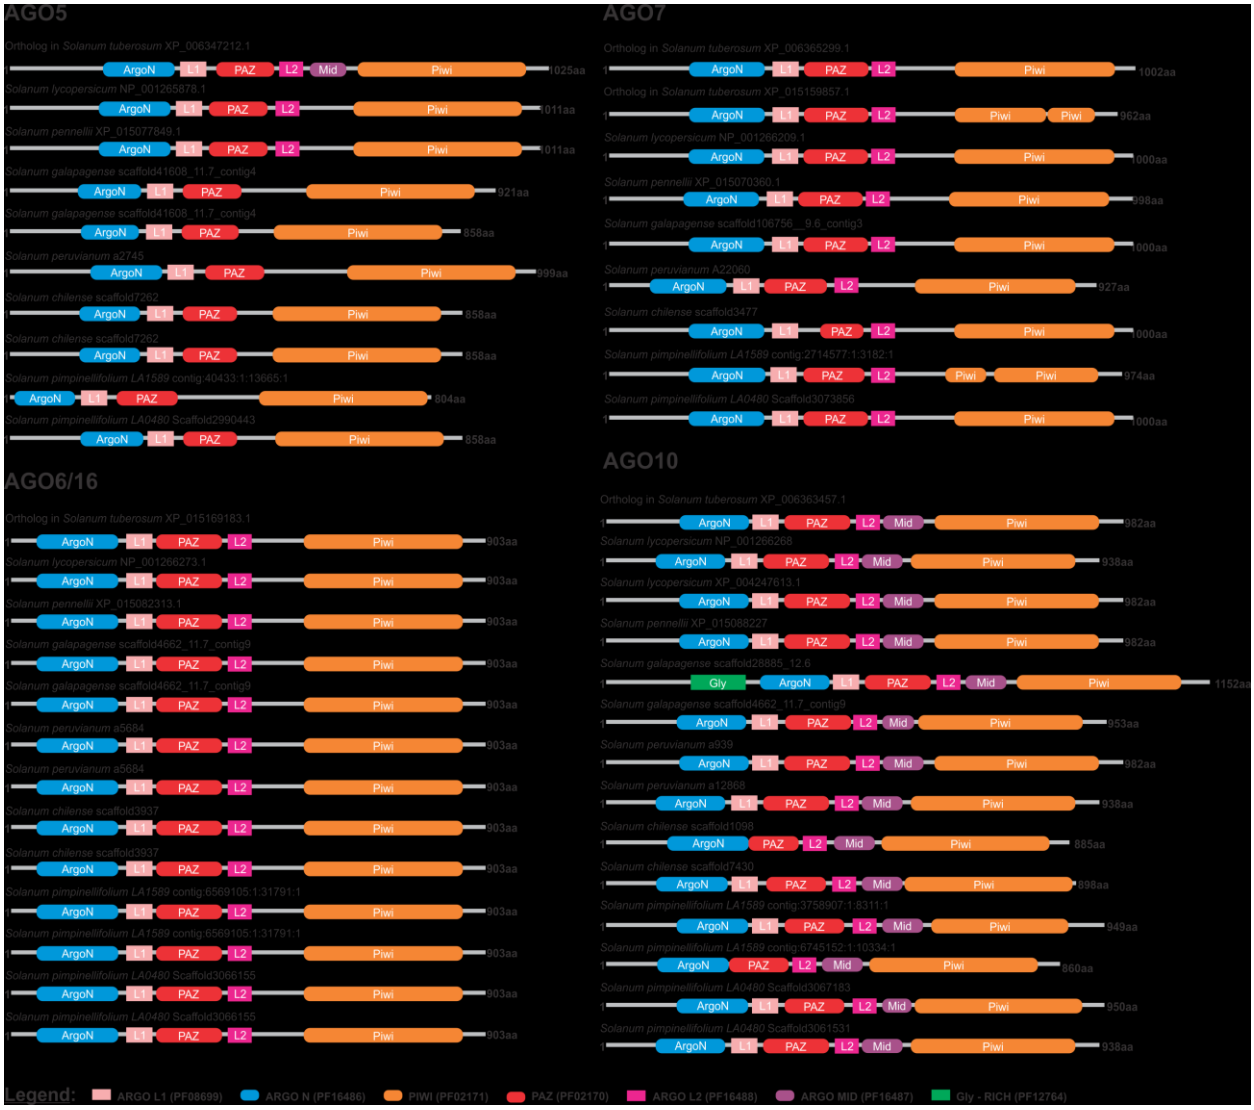

Figure 2 - Distribution of conserved domains in AGO5, AGO6/16, AGO7 and AGO10 putative proteins of *S. lycopersicum*, *S. pennellii, S. galapagense, S. chilense, S. peruvianum*, *S. pimpinellifolium* LA0480, *S. pimpinellifolium* LA1589 and their ortholog in *S. tuberosum.*

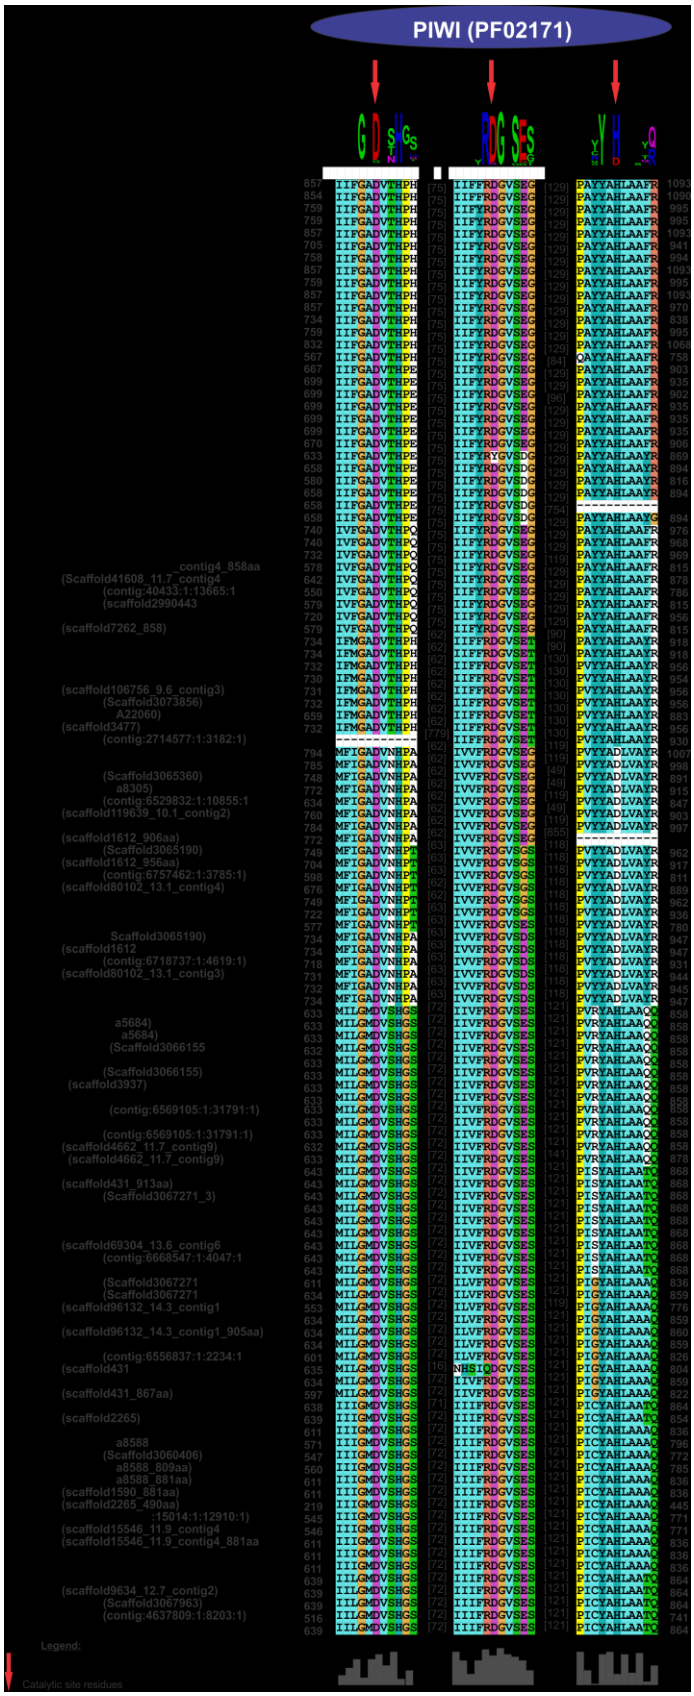
The Piwi conserved domain, one of the main domains present in AGO proteins, was identified in all AGO proteins of the species studied. These domains showed active site regions containing an important catalytic triad DDH (aspartate/aspartate/histidine) in all AGO pronteins, except AGO2 protein that showed active site regions the catalytic triad DDD (aspartate/aspartate/aspartate). The scaffold104755_11.7_contig5 of the SgaAGO10 exhibited the catalytic triad DYD (aspartate/tyrosine/histidine). Moreover, the SchAGO10 (scaffold7430) and

SchAGO2 (scaffold1612_906aa) showed truncated at the end and the SpiLA1589 AGO7 (contig:2714577:1:3182:1) at the beginning of the sequence (Figure 3).



60 **Figure 3 -** Weblogo analysis and sequence multiple alignment of active site amino
61 acids and their flanking amino acid residues in the PIWI conserved domain of *S.*
62 *lycopersicum* (Sly), *S. pennellii* (Spe), *S. galapagense* (Sga), *S. chilense* (Sch), *S.*
63 *peruvianum* (Spr), *S. pimpinellifolium* LA0480 (SpiLA0480), *S. pimpinellifolium* LA1589
64 (SpiLA1589) and their ortholog in *S. tuberosum*. The red arrows show the amino acid
65 residues of the active sites (catalytic triad: Asp-Asp-His). The height of each amino acid
66 symbol in Weblogo indicates amino acid residue conservation at a given position.
67
68 We also search the conserved domains of the all DCl proteins in species
69 studied (Figure 4, Figure 5, Figure 6 and Supplementary Table S3). The DCL1
70 proteins of the all species anlised displayed the conserved ResIII (also known as
71 DEAD-like), helicase C, Dicer dimer (also known as DUF283), PAZ, ribonuclease
72 IIIa (RNase IIIa), ribonuclease IIIb (RNase IIIb), dsrm and DND1 DSRM domains
73 (Figure 4 and Supplementary Figure S1 and Supplementary Table S4). We found
74 two RNAse III domains in DCL proteins of the all species of this work, except the
75 SgaDCL2 (Scaffold2617_14.2_contig6), SgaDCL2 (Scaffold2617_14.2_contig4),
76 SchDCL2 (Scaffold2617_14.2_contig7), SchDCL2 (Scaffold6549) and *S.*
77 *pimpinellifolium* LA1589 DCL2 (contig:6660195:1:6613:1). The two domains
78 (RNase IIIa and RNase IIIb) had the same catalytic residues in all tomato species
79 studied: glutamate (E), aspartate (D), aspartate (D), glutamate (E), representing
80 the EDDE active site. The SchDCL2 (Scaffold6549_1335aa) and StuDCL2
81 (XP_015169591.1) proteins did not showed the last catalytic residues (DE) of the
82 active site because it was truncated at the sequence end (Figure 7).
83

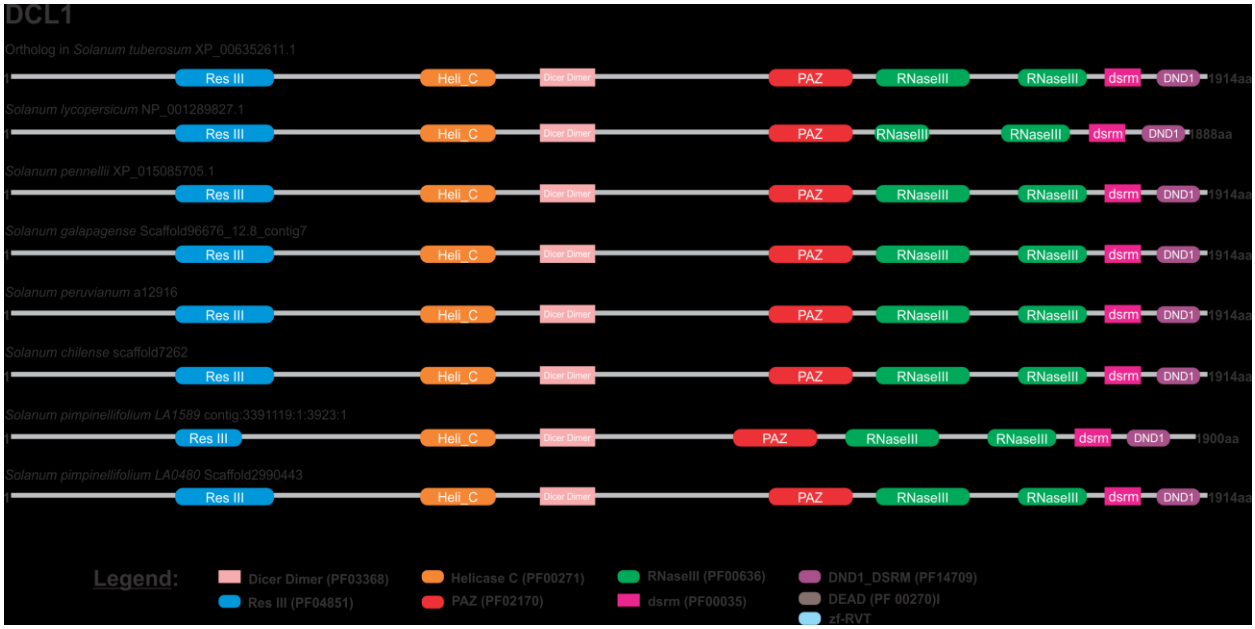


Figure 4 - Distribution of conserved domains in DCL1 putative proteins of *S. lycopersicum*, *S. pennellii, S. galapagense, S. chilense, S. peruvianum*, *S. pimpinellifolium* LA0480, *S. pimpinellifolium* LA1589 and their ortholog in *S. tuberosum.*

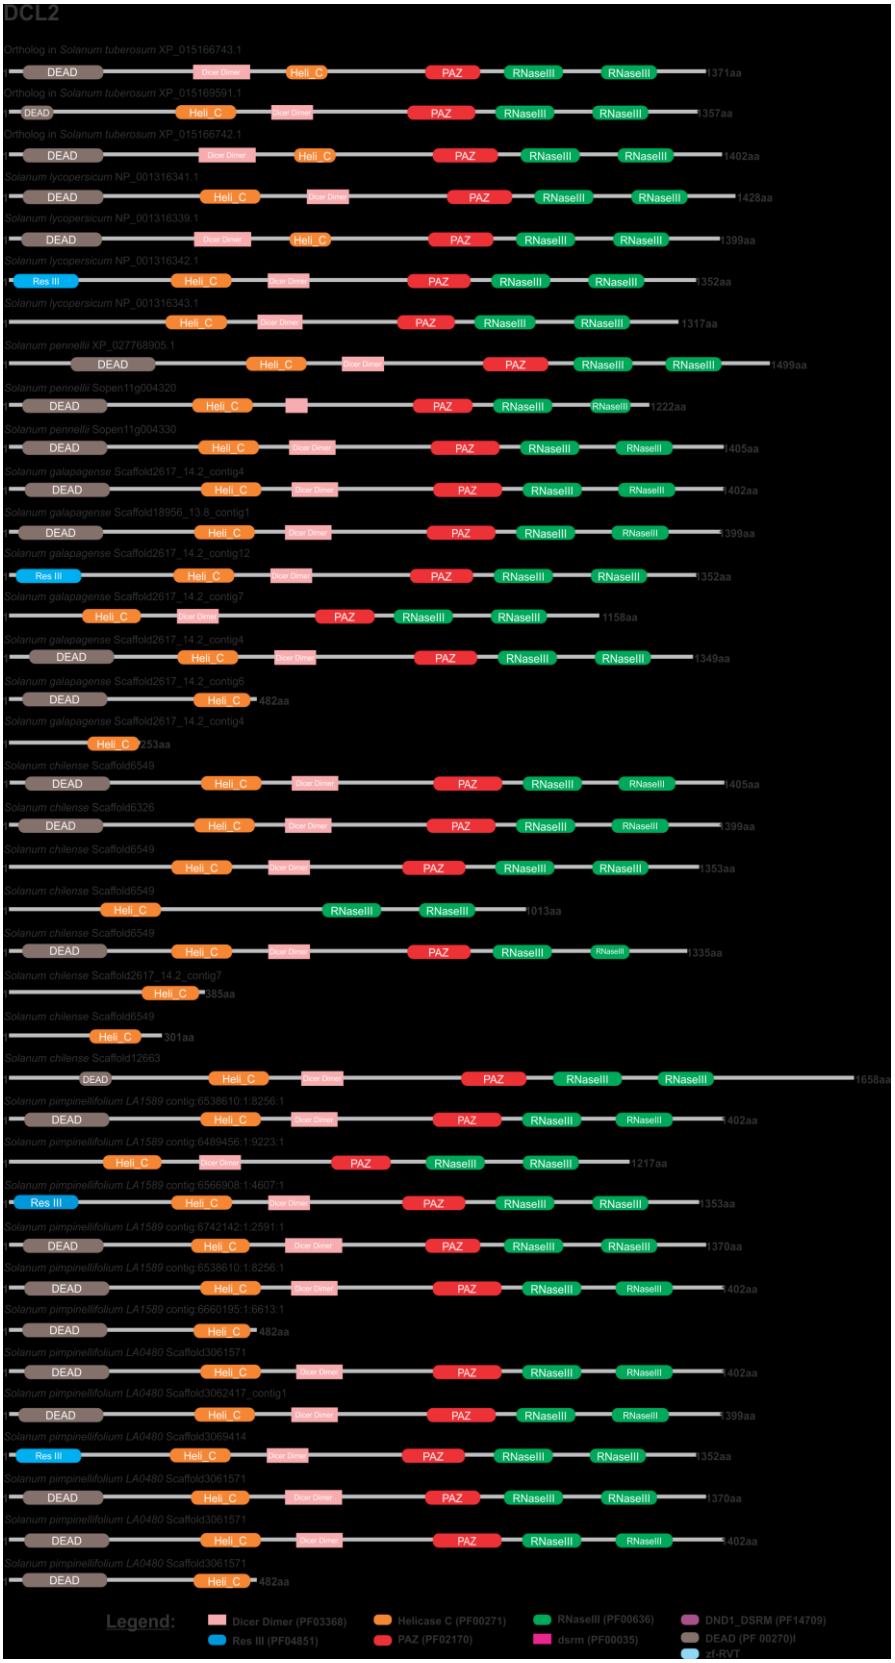

Figure 5 - Distribution of conserved domains in DCL2 putative proteins of *S. lycopersicum*, *S. pennellii, S. galapagense, S. chilense, S. peruvianum*, *S. pimpinellifolium* LA0480, *S. pimpinellifolium* LA1589 and their ortholog in *S. tuberosum.*

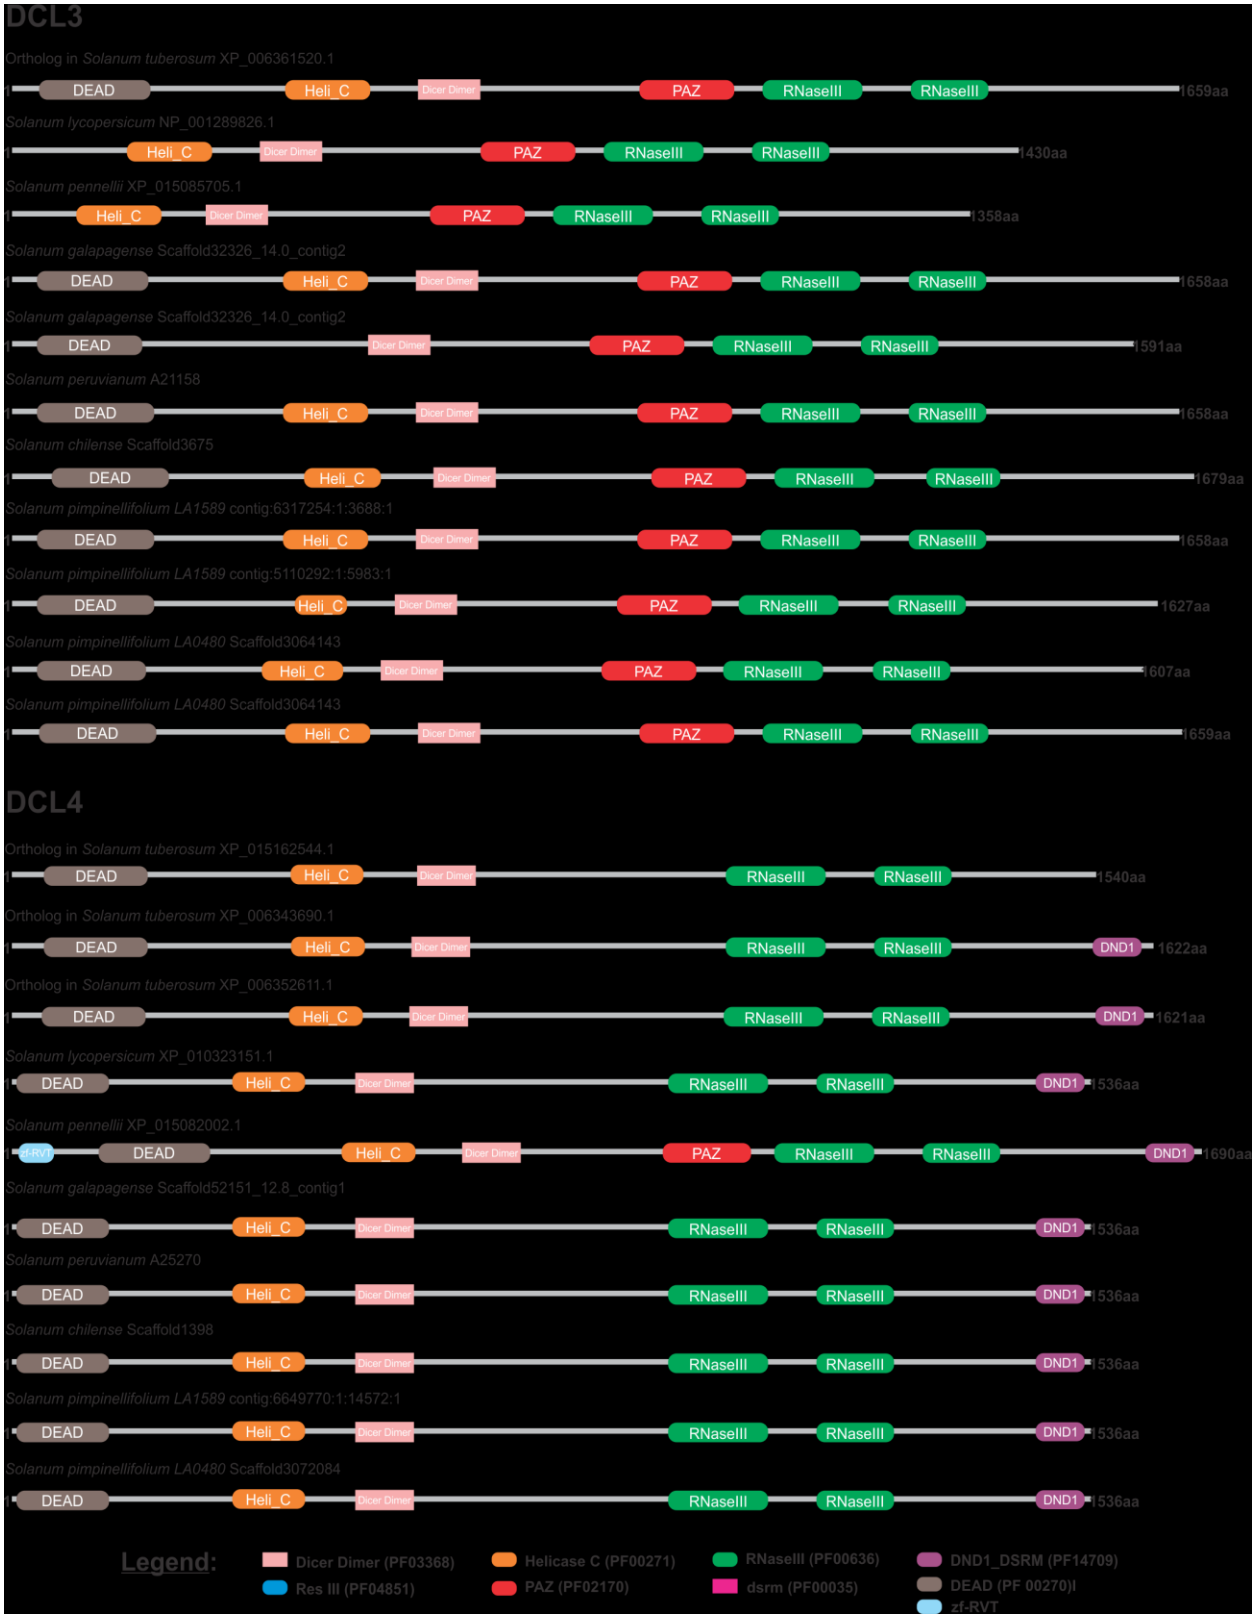

Figure 6 - Distribution of conserved domains in DCL3 and DCL4 putative proteins of *S. lycopersicum*, *S. pennellii, S. galapagense, S. chilense, S. peruvianum*, *S. pimpinellifolium* LA0480, *S. pimpinellifolium* LA1589 and their ortholog in *S. tuberosum.*

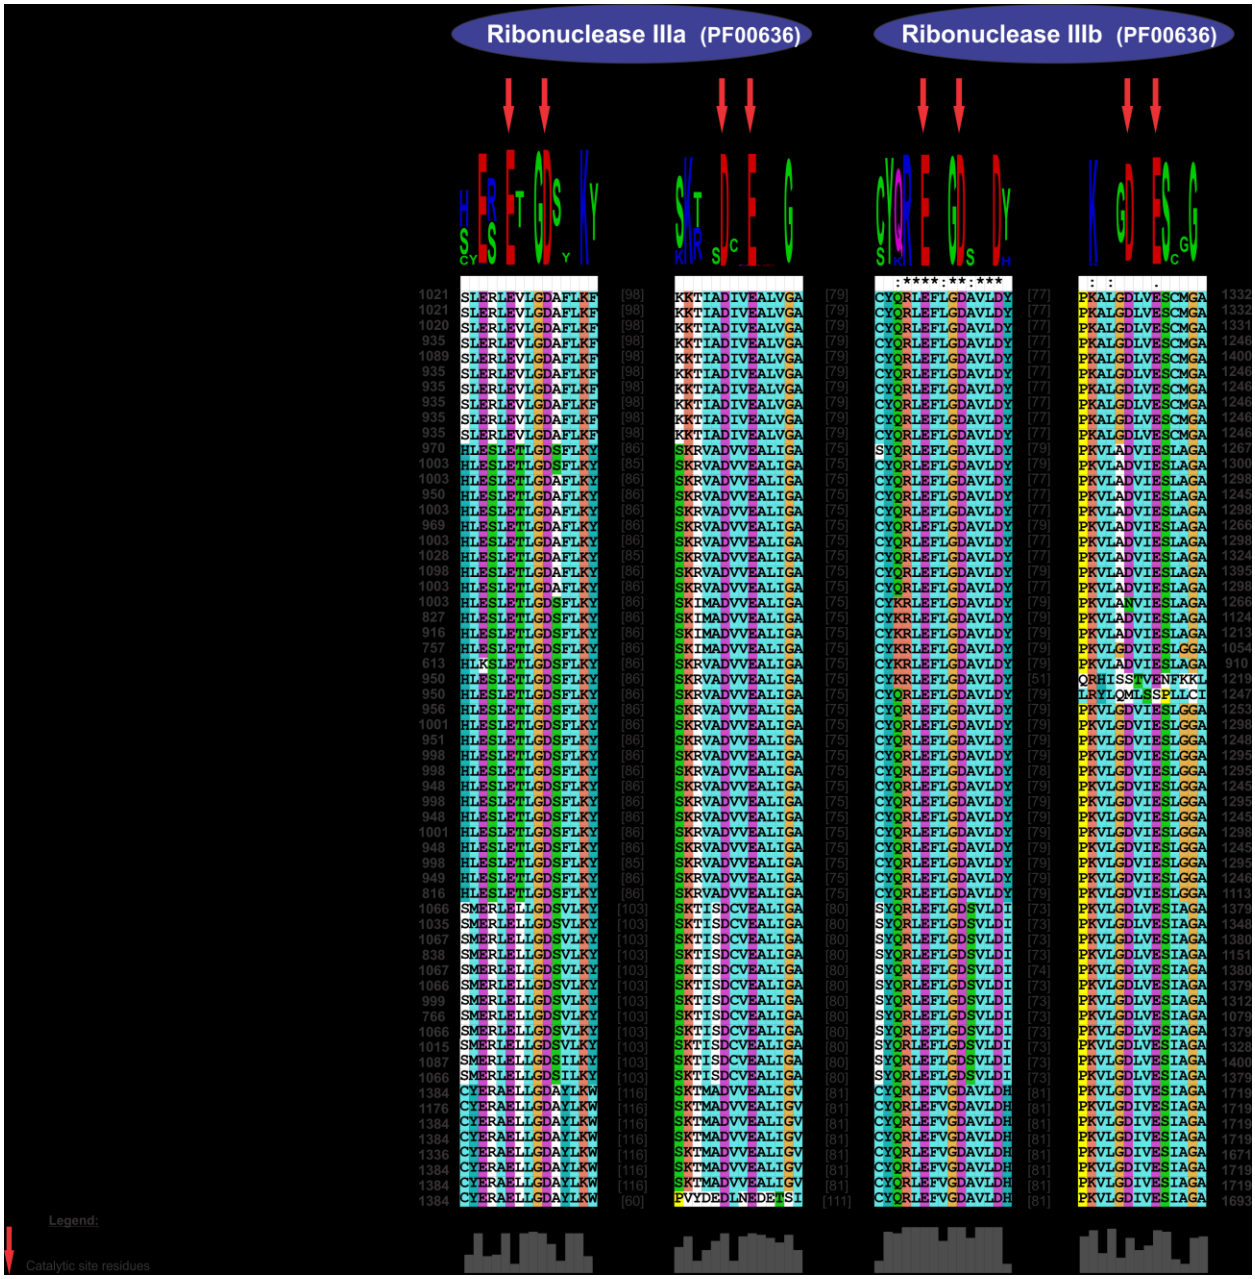

Figure 7 - Weblogo analysis and sequence multiple alignment of active site amino acids and their flanking amino acid residues in the Ribonuclease IIIa and Ribonuclease IIIb conserved domains of *S. lycopersicum* (Sly), *S. pennellii* (Spe), *S. galapagense* (Sga), *S. chilense* (Sch), *S. peruvianum* (Spr), *S. pimpinellifolium* LA0480 (SpiLA0480), *S. pimpinellifolium* LA1589 (SpiLA1589) and their ortholog in *S. tuberosum*. The red arrows show the amino acid residues of the active sites (Glu-Asp-Asp-Glu). The height of each amino acid symbol in Weblogo indicates amino acid residue conservation at a given position.

To understand the diversification of AGO proteins in *S. lycopersicum*, *S. pennellii*, *S. galapagense, S. chilense, S. peruvianum* and *S. pimpinellifolium,* a phylogenetic analysis was performed using their amino acid sequences (Figure 8). The phylogenetic tree was divided into seven distinct clades of paralogous AGOs (AGO1, AGO2, AGO4, AGO5, AGO6, AGO7 and AGO10). The distribution of the seven clades showed a relationship between some paralogous proteins specific to the AGO family, with a great similarity among the AGO1, AGO5 and AGO10 proteins; AGO6 and AGO4; AGO2 and AGO7. The tomato AGO1 and AGO10 proteins showed that they were distributed in the phylogenetic tree closest to their respective orthologous proteins from the plant species *S. tuberosum, Nicotiana attenuata* and *Nicotiniana sylvestris.*

In addition, to determine the evolutionary relationship among the putative DCL proteins of in *S. lycopersicum*, *S. pennellii*, *S. galapagense, S. chilense, S. peruvianum*, *S. pimpinellifolium* and their homologous species, a phylogenetic analysis was also conducted. The proteins were grouped through global alignment in four distinct clades (DCL1, DCL2, DCL3 and DCL4). The distribution among the DCL family paralogous showed a strong correlation between the DCL1 and DCL2 proteins, being also close to DCL4 and further away from DCL3 (Figure 9).

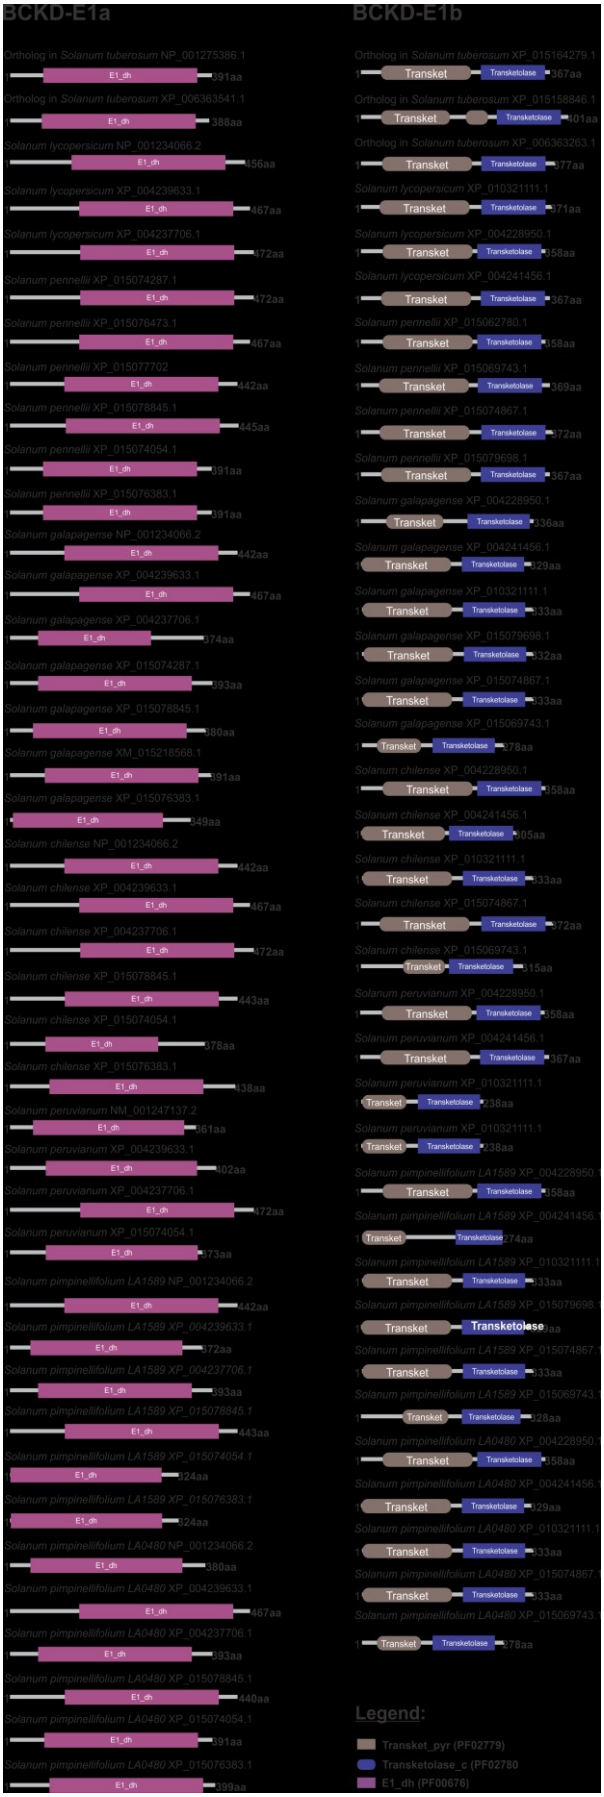
136 **BCKD, IPMS and AT proteins**

137

138 In the same way of the small RNA pathway proteins, through BLASTn tool,
139 we made the prediction and characterization of the acylsugar pathway proteins in
140 *S. galapagense, S. chilense, S. peruvianum* and *S. pimpinellifolium* genomes,
141 using 61 mRNA of *S. lycopersicum* and *S. pennellii*, previously identified
142 (Genome-wide identification and characterization of genes involved in the
143 acylsugar pathway in tomato). Were identified 5 IPMS, 11 BCKD and 21 AT
144 proteins in *S. galapagense*, 1 IPMS, 8 BCKD and 1 AT in *S. peruvianum,* 8 IPMS,
145 12 BCKD and 18 AT in *S. chilense,* 4 IPMS, 5 BCKD and 21 AT in *S.*
146 *pimpinellifolium* LA1589 and 4 IPMS, 10 BCKD and 21 AT proteins in *S.*
147 *pimpinellifolium* LA0480 (Supplementary Table S4).

148 Among all putative proteins identified, the putative protein families BCKD
149 E2, IPMSA, and AT were considered key proteins in the processing machinery of
150 acylsugars (Kandra et al. 1990; Walters and Steffens 1990; Slocombe et al. 2008;
151 Ning et al. 2015; Schilmiller et al. 2015; Fan et al. 2016, 2017). We found 1 BCKD
152 E2 proteins in all tomato species studied, 3 IPMSA proteins in *S. pimpinellifolium*
153 LA1589 and *S. pimpinellifolium* LA1589 as in *S. lycopersicum,* 4 in *S.*
154 *galapagense,* 6 in *S. chilense* and none in *S. peruvianum.* In addition, we also
155 found 2 AT2 proteins in *S. galapagense, S. chilense, S. pimpinellifolium,* none in
156 *S. peruvianum*; 19 AT3 proteins in *S. galapagense, S. pimpinellifolium* LA1589, *S.*
157 *pimpinellifolium* LA1589; 16 and 1 AT3 pronteins in *S. chilense* and *S.*
158 *peruvianum,* respectively (Supplementary Table S4).

159 The distribution of the conserved domains of the all BCKD and IPMS
160 proteins were search in the tomato species analised (Figure 10, Figure 11, Figure
161 12, Supplementary Figure S5 and Supplementary Table S6). Furthermore,
162 position of the amino acids from active sites (Figure 13 and Figure 14) and the
163 phylogenetic distribution (Figure 15 and Figure 16) of the putative tomato proteins
164 BCKD E2 and IPMS were obtained compared to the reference homologous
165 proteins from other plant species.



BCKD-E1a
BCKD-E1b
Legend:
Transket_pyr (PF02779)
Transketolase_c (PF02780
E1_dh (PF00676)

Figure 10 - Distribution of conserved domains in BCKD E1a and BCKD E1b putative proteins of *S. lycopersicum*, *S. pennellii, S. galapagense, S. chilense, S. peruvianum*, *S. pimpinellifolium* LA0480, *S. pimpinellifolium* LA1589 and their ortholog in *S. tuberosum.*

The BCKD E2 proteins of *S. lycopersicum*, *S. pennellii*, *S. galapagense, S. chilense, S. peruvianum*, *S. pimpinellifolium* and ortholog *S. tuberosum* displayed the domains Biotin_lipoyl, E3_binding and 2-oxoacid_dh (Figure 11 and Supplementary Figure S5). The Biotin_lipoyl conserved domain is one of the main domains contained in the BCKD E2 proteins. It was also shown that the active sites contained the important catalytic residue K (lysine) in a specific and conserved position (Figure 13). The conserved domains and active sites found in BCKD E2 proteins of the all tomato species studied showed high conservation compared to the BCKD E2 proteins in other plant species, such as *S. tuberosum* and *A. thaliana*.

Figure 11 - Distribution of conserved domains in BCKD E2 putative proteins of *S. lycopersicum*, *S. pennellii, S. galapagense, S. chilense, S. peruvianum*, *S. pimpinellifolium* LA0480, *S. pimpinellifolium* LA1589 and their ortholog in *S. tuberosum.*

188 Another important catalytic component of the acylsugar processing pathway
189 in plants are the IPMSA proteins. The conserved domains HMGL-like and
190 LeuA_imer were the main domains found in tomato and *S. tuberosum* IPMSA and
191 IPMB proteins. In all IPMSB proteins and SlyIPMSA (NP_001316379.1),
192 SpeIPMSA (NP_001310380.1), SgaIPMSA (scaffold90874_8.2_contig_2 and
193 scaffold90874_8.2_contig_2), SchIPMSA (scaffold7114), SpiLA1589 IPMSA
194 (contig:921951:1:3418:1) and SpiLA0480 IPMSA (Scaffold2425123) contained the
195 HMGL-like and LeuA_imer domains; the other IPMSA proteins presented only the
196 HMGL-like domain (Figure 12 and Supplementary Table S6).

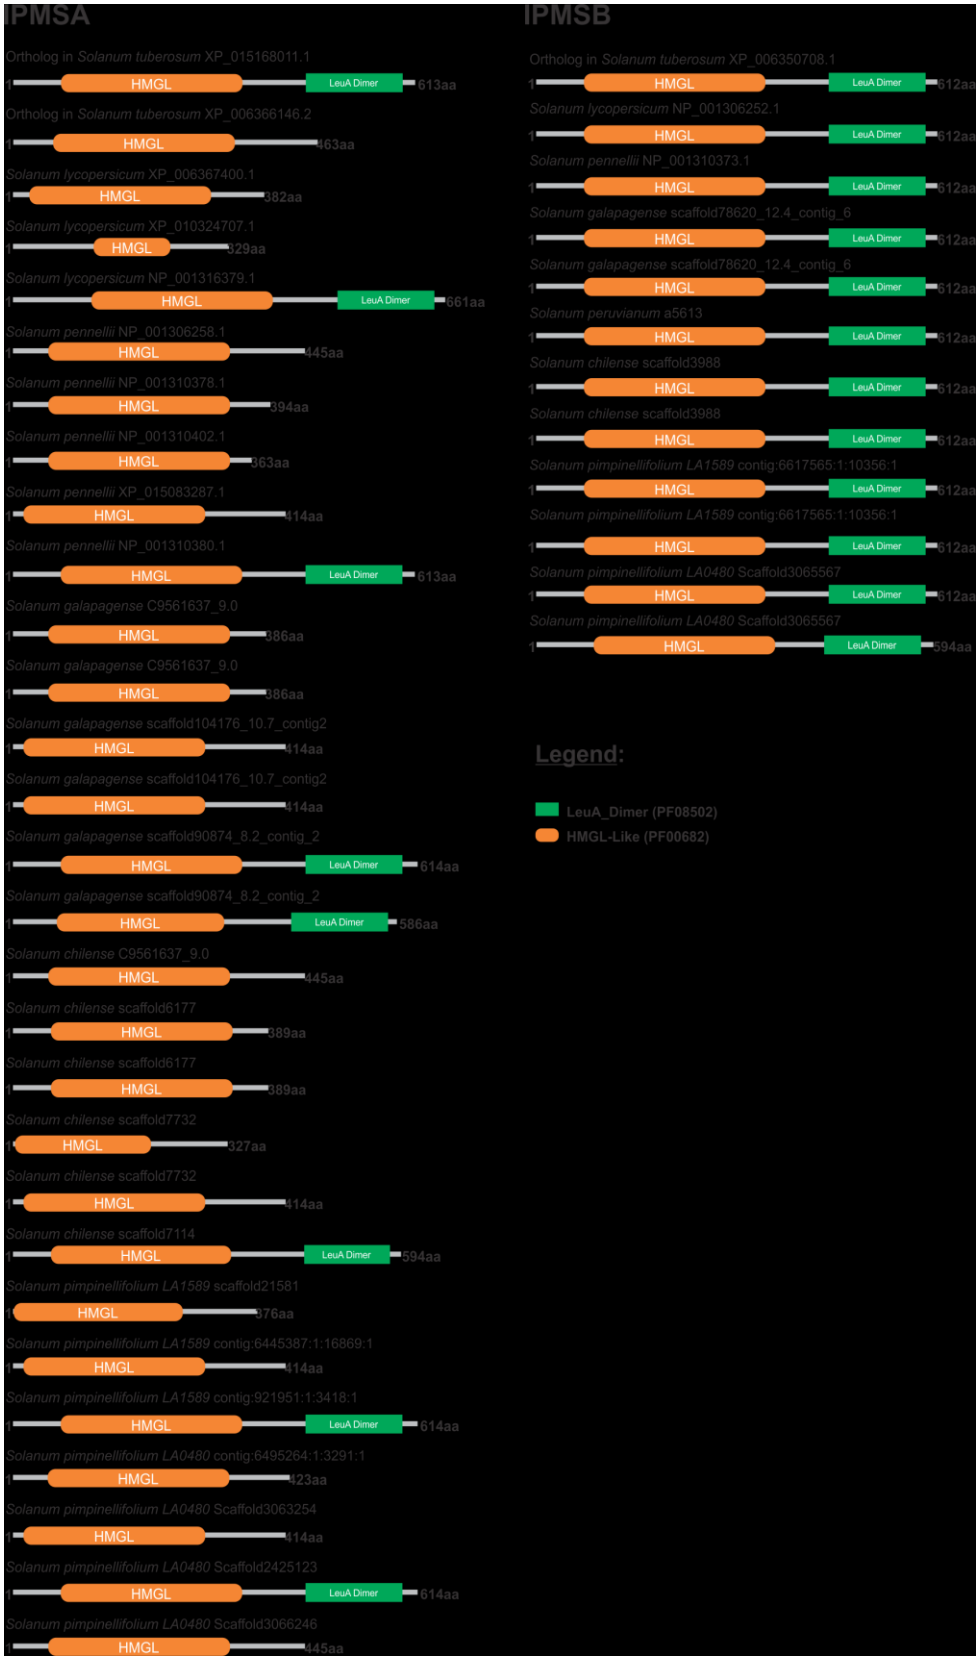


Figure 12 - Distribution of conserved domains in IPMSA and IPMSB putative proteins of *S. lycopersicum*, *S. pennellii, S. galapagense, S. chilense, S. peruvianum*, *S. pimpinellifolium* LA0480, *S. pimpinellifolium* LA1589 and their ortholog in *S. tuberosum.*

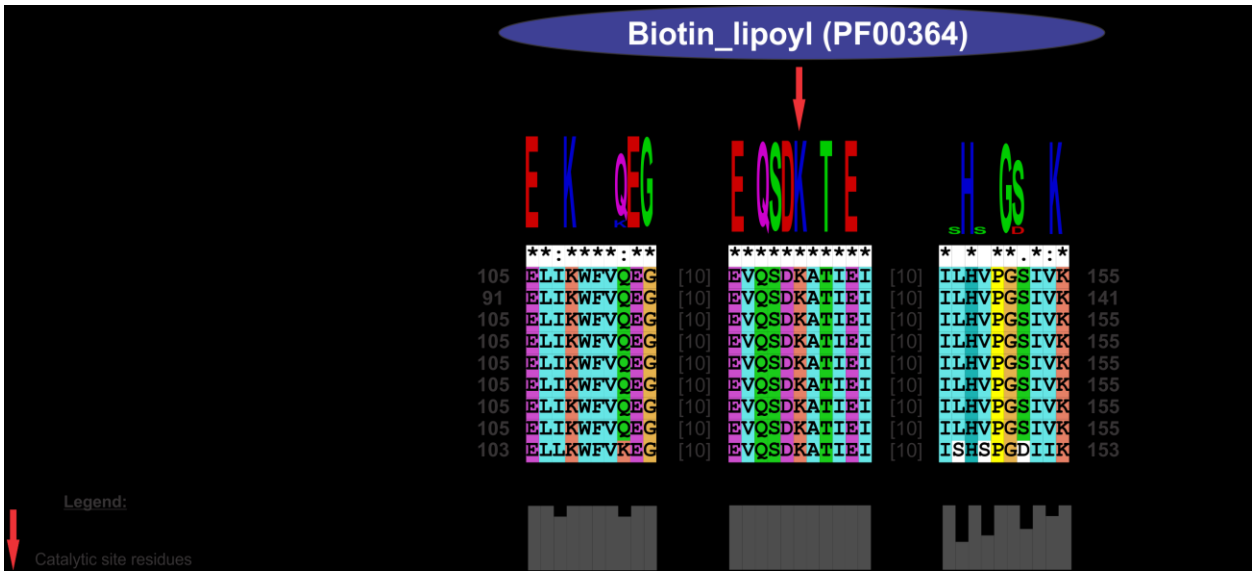

Figure 13 - Weblogo analysis and sequence multiple alignment of active site amino acids and their flanking amino acid residues in the Biotin_lipoyl conserved domains of *S. lycopersicum* (Sly), *S. pennellii* (Spe), *S. galapagense* (Sga), *S. chilense* (Sch), *S. peruvianum* (Spr), *S. pimpinellifolium* LA0480 (SpiLA0480), *S. pimpinellifolium* LA1589 (SpiLA1589) and their ortholog in *S. tuberosum*. The red arrows show the amino acid residues of the active sites (lysine). The height of each amino acid symbol in Weblogo indicates amino acid residue conservation at a given position.

The HMGL-like domains in all tomato species showed the same catalytic residues, aspartate (D), arginine (R) and glutamate (E), and these of catalytic triad (DRE), corroborating with IPMSA proteins of *S. tuberosum* (Figure 14). Only SchIPMSA (scaffold21581), SprIPMSA (a5613) and SchIPMSA (scaffold7732_327aa) proteins did not showed the first catalytic residue (D) of the active site because it was truncated at the beginning of the sequence.

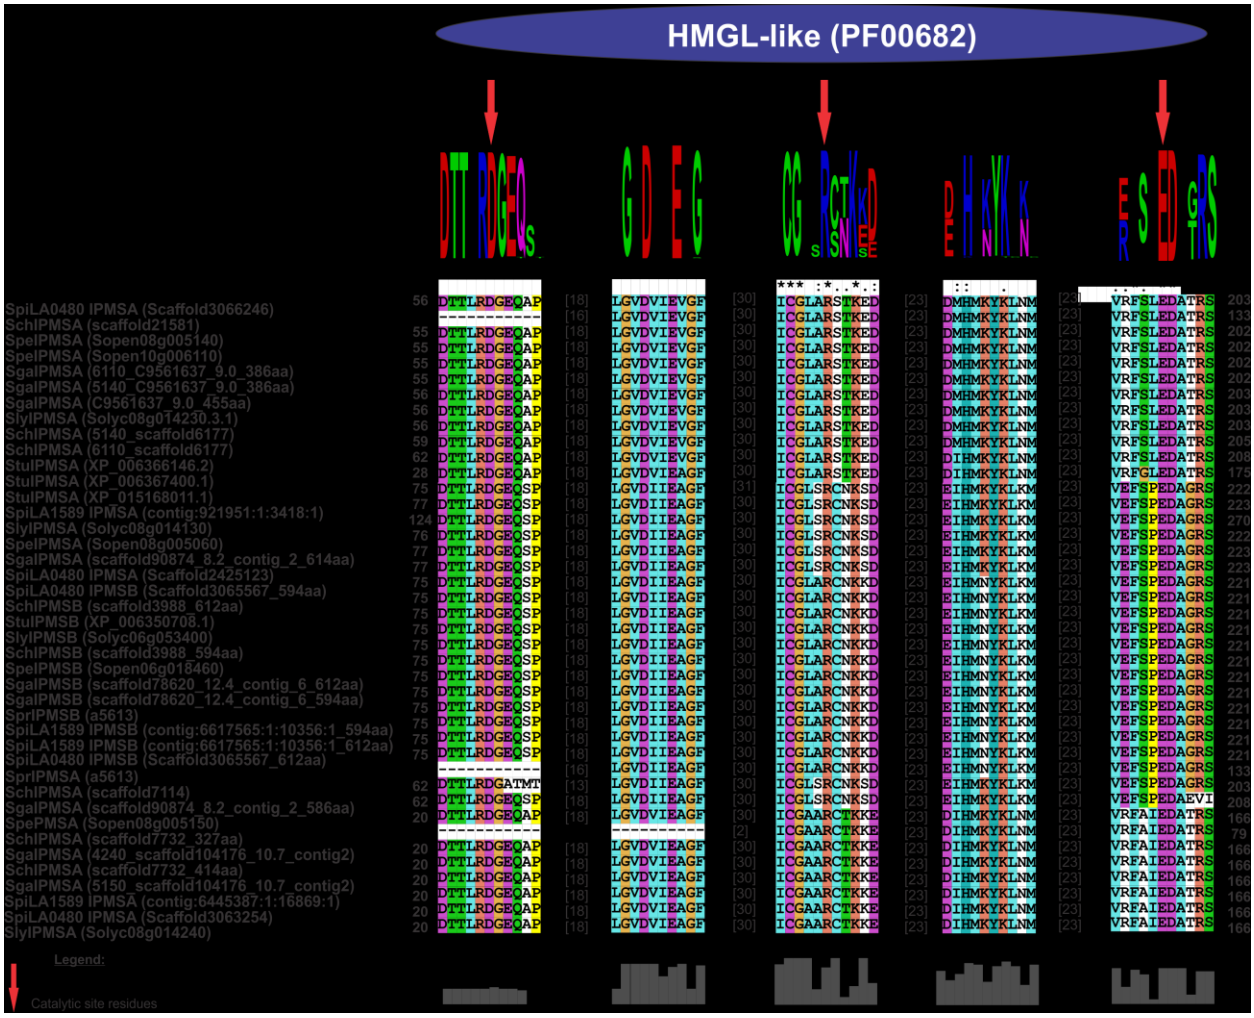

Figure 14 - Weblogo analysis and sequence multiple alignment of active site amino acids and their flanking amino acid residues in the HMGL-like conserved domains of *S. lycopersicum* (Sly), *S. pennellii* (Spe), *S. galapagense* (Sga), *S. chilense* (Sch), *S. peruvianum* (Spr), *S. pimpinellifolium* LA0480 (SpiLA0480), *S. pimpinellifolium* LA1589 (SpiLA1589) and their ortholog in *S. tuberosum*. The red arrows show the amino acid residues of the active sites (asp-arg-glu). The height of each amino acid symbol in Weblogo indicates amino acid residue conservation at a given position.

The phylogenetic distribution of BCKD (Figure 15) and IPMS (Figure 16) proteins was performed using amino acid sequences. The phylogenetic analysis of the BCKD proteins showed that these putative proteins were distributed in the phylogenetic tree closest to their respective ortholog proteins of the *Solanaceae,* as *Capsicum annuum*, *S. tuberosum, N. attenuate, N. tabacum* and *N. sylvestris.* The phylogenetic tree was divided into clades of 3 distinct: BCKD E2, BCKD E1a and BCKD E1b, and distributed among families *Solanaceae, Vitaceae, Rosaceae,*

233 *Malvaceae, Rubiaceae, Rutaceae, Myrtaceae, Fabaceae* and *Brassicaceae*
234 (Figure 15). To determine the evolutionary relationship among the putative tomato
235 IPMS proteins and their orthologs a phylogenetic analysis was performed (Figure
236 16). The proteins were grouped in IPMSA and IPMSB. The *Solanaceae* protein
237 family containing the tomato proteins and their orthologous of *S. tuberosum, N.*
238 *attenuate, N. tabacum* and *N. sylvestris* was well separated from the *Brassicaceae*
239 family on the tree.

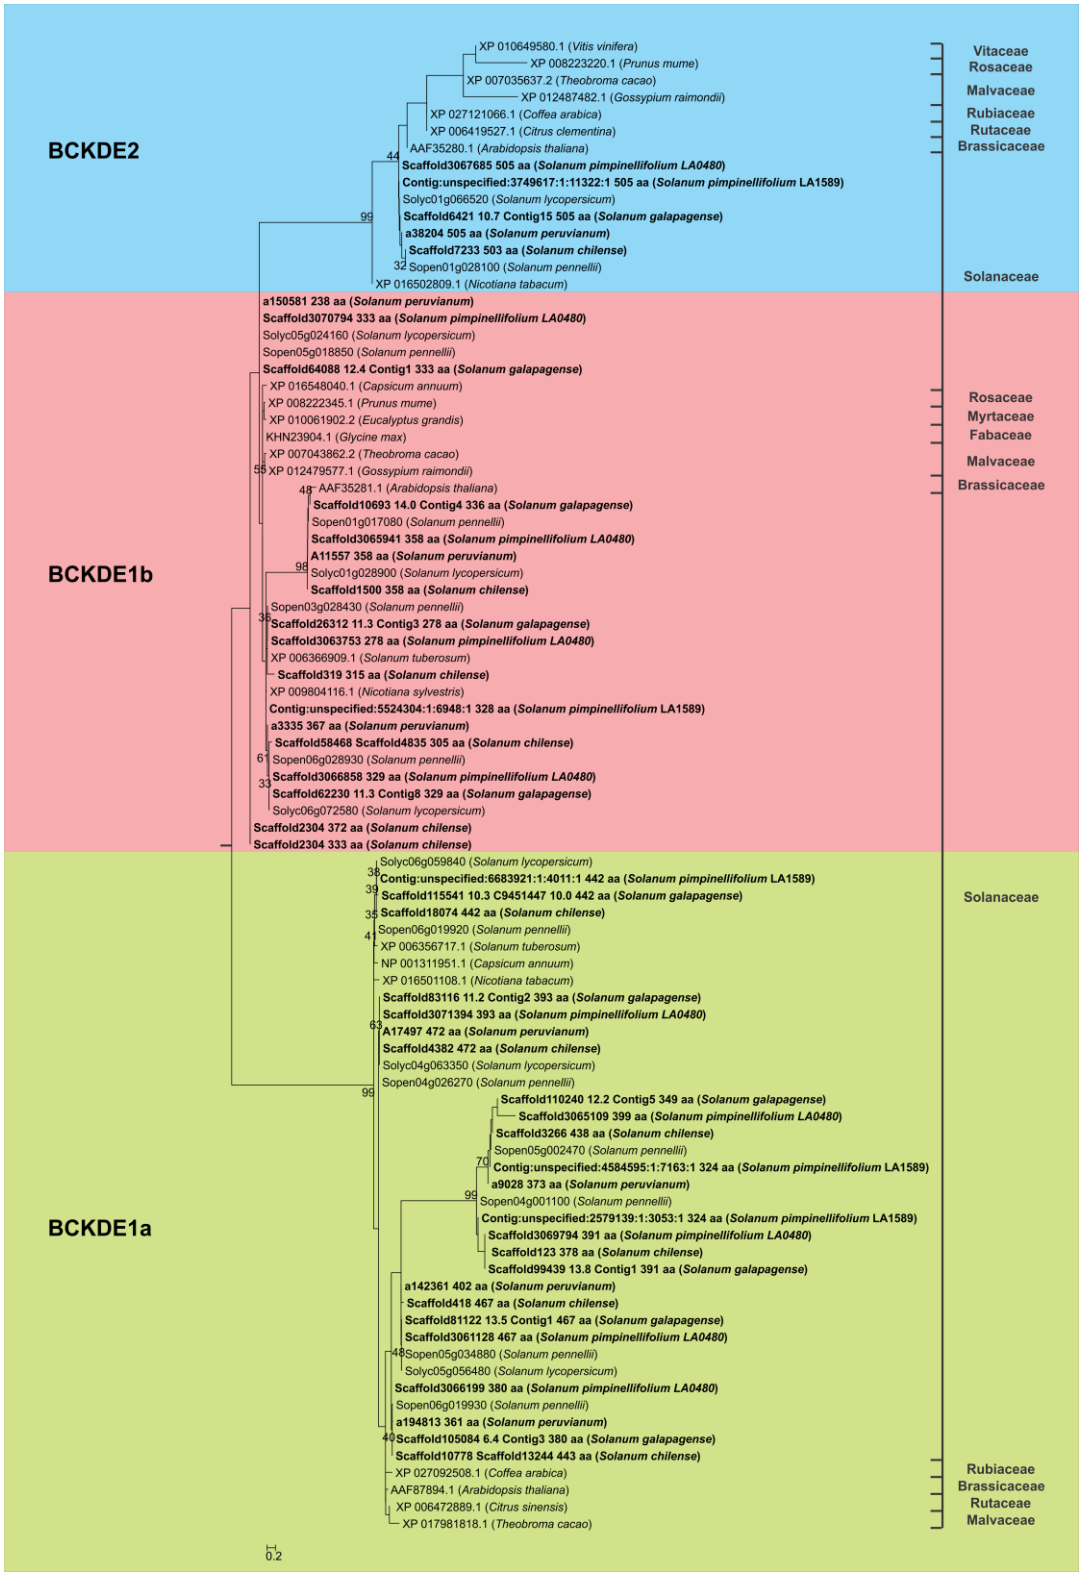

Figure 15 - Phylogenetic tree of BCKD proteins identified in *S. lycopersicum*, *S. pennellii, S. galapagense, S. chilense, S. peruvianum*, *S. pimpinellifolium* LA0480, *S. pimpinellifolium* LA1589 and their orthologs.

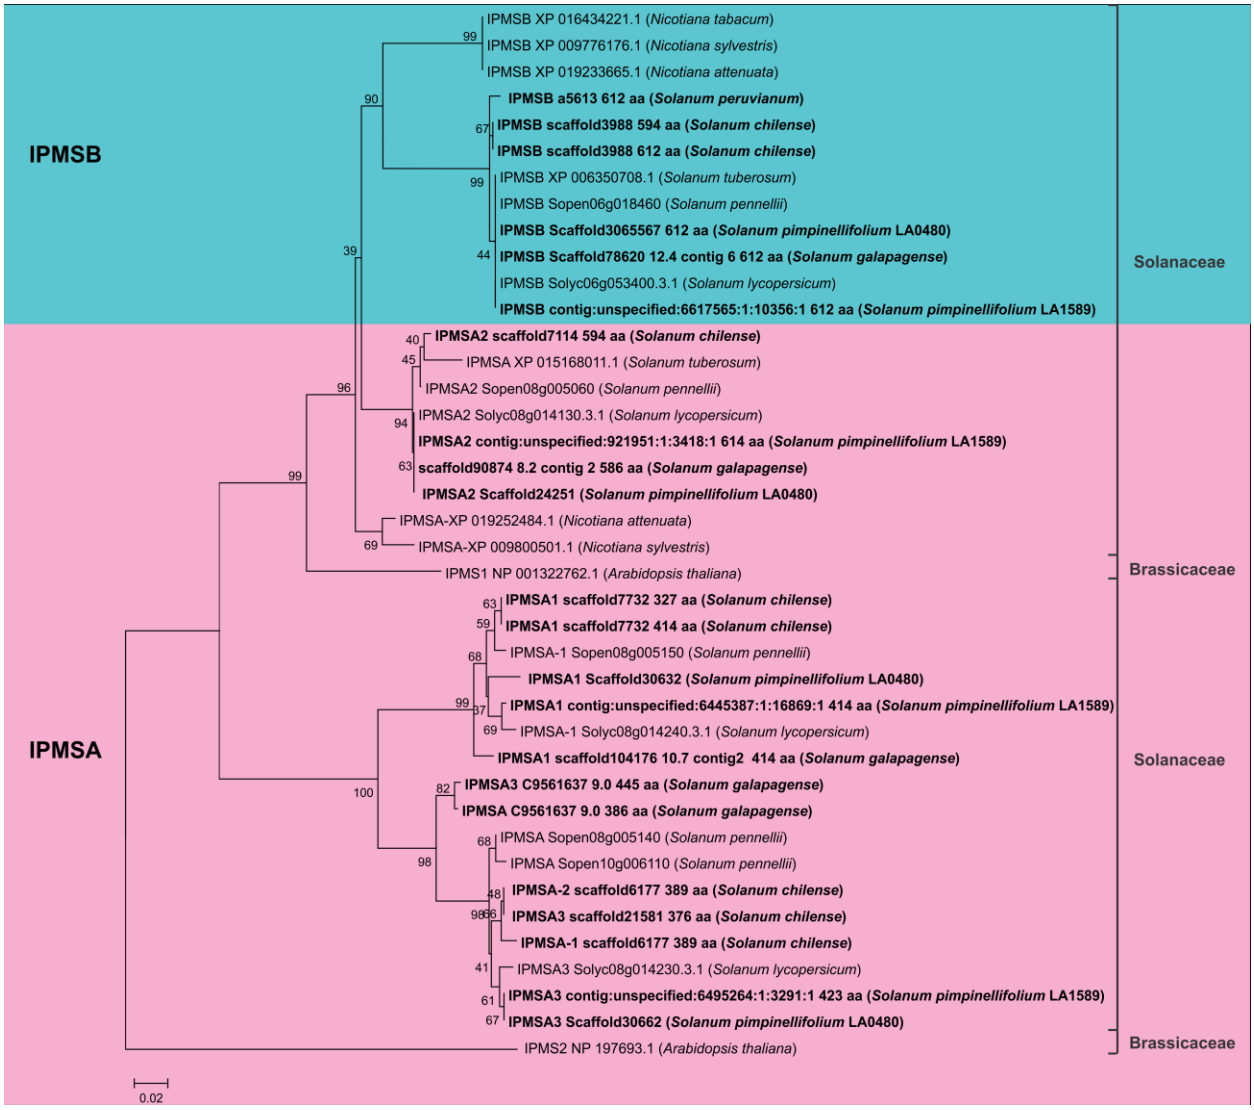

Figure 16 - Phylogenetic tree of IPMS proteins identified in *S. lycopersicum*, *S. pennellii, S. galapagense, S. chilense, S. peruvianum*, *S. pimpinellifolium* LA0480, *S. pimpinellifolium* LA1589 and their orthologs.

Mature miRNAs and their precursors in *S. lycopersicum*, *S. pennellii, S. galapagense, S. chilense, S. peruvianum* and *S. pimpinellifolium*

We identify both mature and precursor sequences of miRNAs in *S. lycopersicum*, *S. pennellii, S. galapagense, S. chilense, S. peruvianum*, *S. pimpinellifolium* LA0480 and *S. pimpinellifolium* LA1589 genomes. By applying an optimized and specific algorithm, we identified 1081 sequences (3p and 5p) of mature miRNAs and 917 precursor miRNAs, distributed in 393 distinct miRNA families in *S. lycopersicum* genome (Supplementary Table S7). In *S. pennellii*,

258 1006 sequences of mature miRNAs were identified and 850 precursor miRNAs
259 were contained in 354 different miRNA families (Supplementary Table S8). *S.*
260 *galapagense* showed 909 mature miRNAs and 760 precursors in 373 families
261 (Supplementary Table S9). In addition, *S. chilense* exhibited 1424 mature miRNAs
262 and 889 precursors in 369 miRNA families (Supplementary Table S10) and *S.*
263 *peruvianum* presented 52 miRNAs mature sequences, 52 precursors in 32 families
264 (Supplementary Table S11). Finally, we searched 1170 mature miRNAs and 1005
265 pré-miRNAs in 446 *S. pimpinellifolium* LA0480 families (Supplementary Table
266 S12) and 1375 mature miRNAs sequences and 865 precursor in 365 different
267 miRNA families of *S. pimpinellifolium* LA1589 (Supplementary Table S13).
268 All identified miRNAs were analysed for their structural and thermodynamic
269 characteristics. *S. lycopersicum* miRNA precursors displayed an MFE with the
270 mean of -59.17 kcal/mol, spanning the values between -99.9 and -20.5 kcal/mol.
271 Such parameters as AMFE and MFEI, had the averages of -35.77 kcal/mol and of
272 -0.99, respectively (Supplementary Table S14). In *S. pennellii*, the pre-miRNAs
273 showed an MFE with the mean of -59.68 kcal/mol, with the values between -99.9
274 and -20.7 kcal/mol, the mean AMFE was -36.37 Kcal/mol and that of MFEI was -
275 0.99 (Supplementary Table S15). *S. galapagense* showed an average MFE,
276 AMFE and MFEI of the -56.36 kcal/mol, -35.60 kcal/mol and 0.97 kcal/mol,
277 respectively (Supplementary Table S16). *S. chilense* miRNA precursors exhibited
278 an MFE with the mean of -55.90 kcal/mol, spanning the values between -99.9 and
279 -20.6 kcal/mol, the mean AMFE was -36.43 Kcal/mol and that of MFEI was -0.99
280 (Supplementary Table S17). In addition, the pre-miRNAs of the *S. peruvianum*
281 (Supplementary Table S18), *S. pimpinellifolium* LA0480 (Supplementary Table
282 S19) and *S. pimpinellifolium* LA1589 (Supplementary Table S20) showed an
283 average MFE of the -51.49 Kcal/mol, -58.19 Kcal/mol and -57.70 Kcal/mol;
284 average AMFE of the -34.12 Kcal/mol, -36.27 Kcal/mol and -35.70 Kcal/mol; and
285 an average MFEI of the -0.85 Kcal/mol, -0.99 Kcal/mol and -0.96 Kcal/mol,
286 respectively.
287 Among the all miRNA families identified in the 7 species under study, we
288 highlighted 5 families for more in-depth characterization, since the MIR165/166
289 family are miRNAs conserved in plants, and the MIR5303, MIR6022 and MIR7981
290 are miRNAs found only in the *Solanaceae* family; and MIR10528 was found only in

tomato species. We analysed the sequences conservation of the MIR6022 (Figure 17) and MIR10528 (Figure 18) miRNAs families. In addition, we did the phylogenetic analysis of the MIR165/166 (Figure 19), MIR5303 (Figure 20), MIR6022 (Figure 21), MIR7981 (Figure 22) and MIR10528 (Figure 23) families.

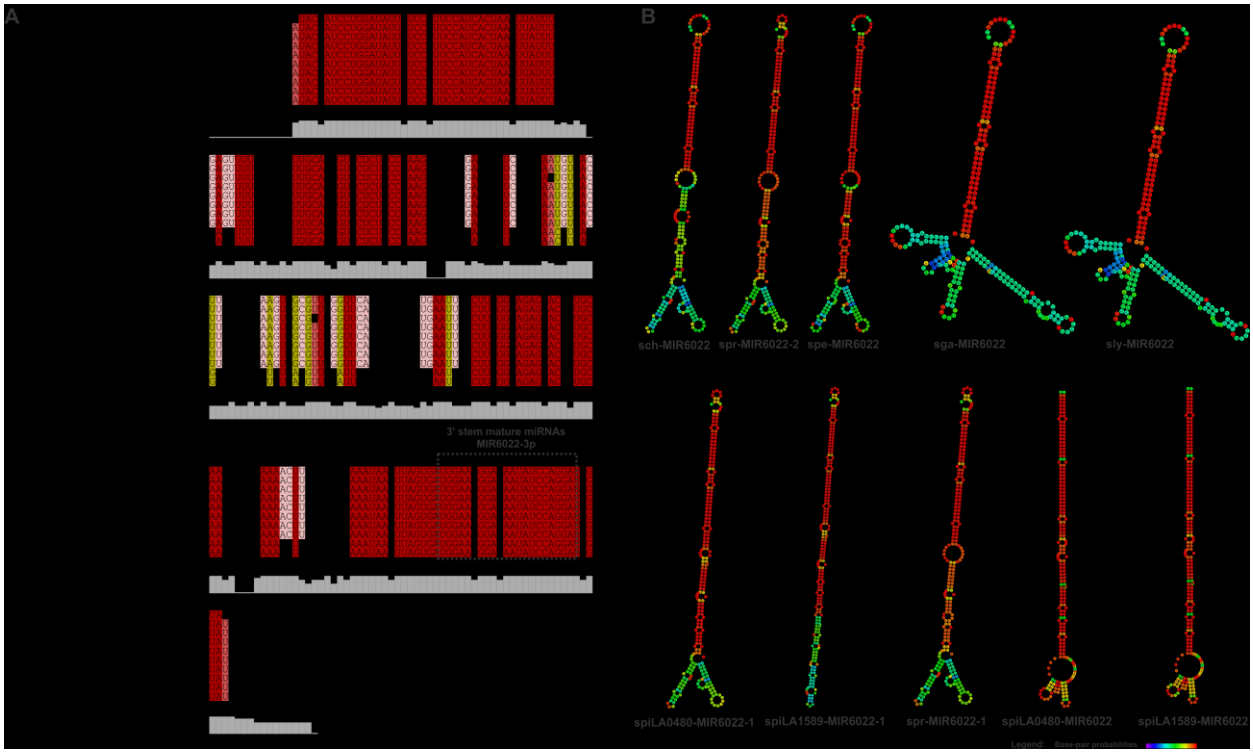

Figure 17 - (A) The high-confidence RNA alignments between MIR6022 families of *S. lycopersicum* (Sly), *S. pennellii* (Spe), *S. galapagense* (Sga), *S. chilense* (Sch), *S. peruvianum* (Spr), *S. pimpinellifolium* LA0480 (SpiLA0480) and *S. pimpinellifolium* LA1589 (SpiLA1589) were performed using RNAalifold. Mature miRNAs are shown as boxes. Brackets and colours identify matching residues in 3' stems of hairpin structures. Levels of nucleotide identity are indicated below the alignment. **(b)** Secondary structures of MIR6022 family from tomato were drawn by RNAfold.

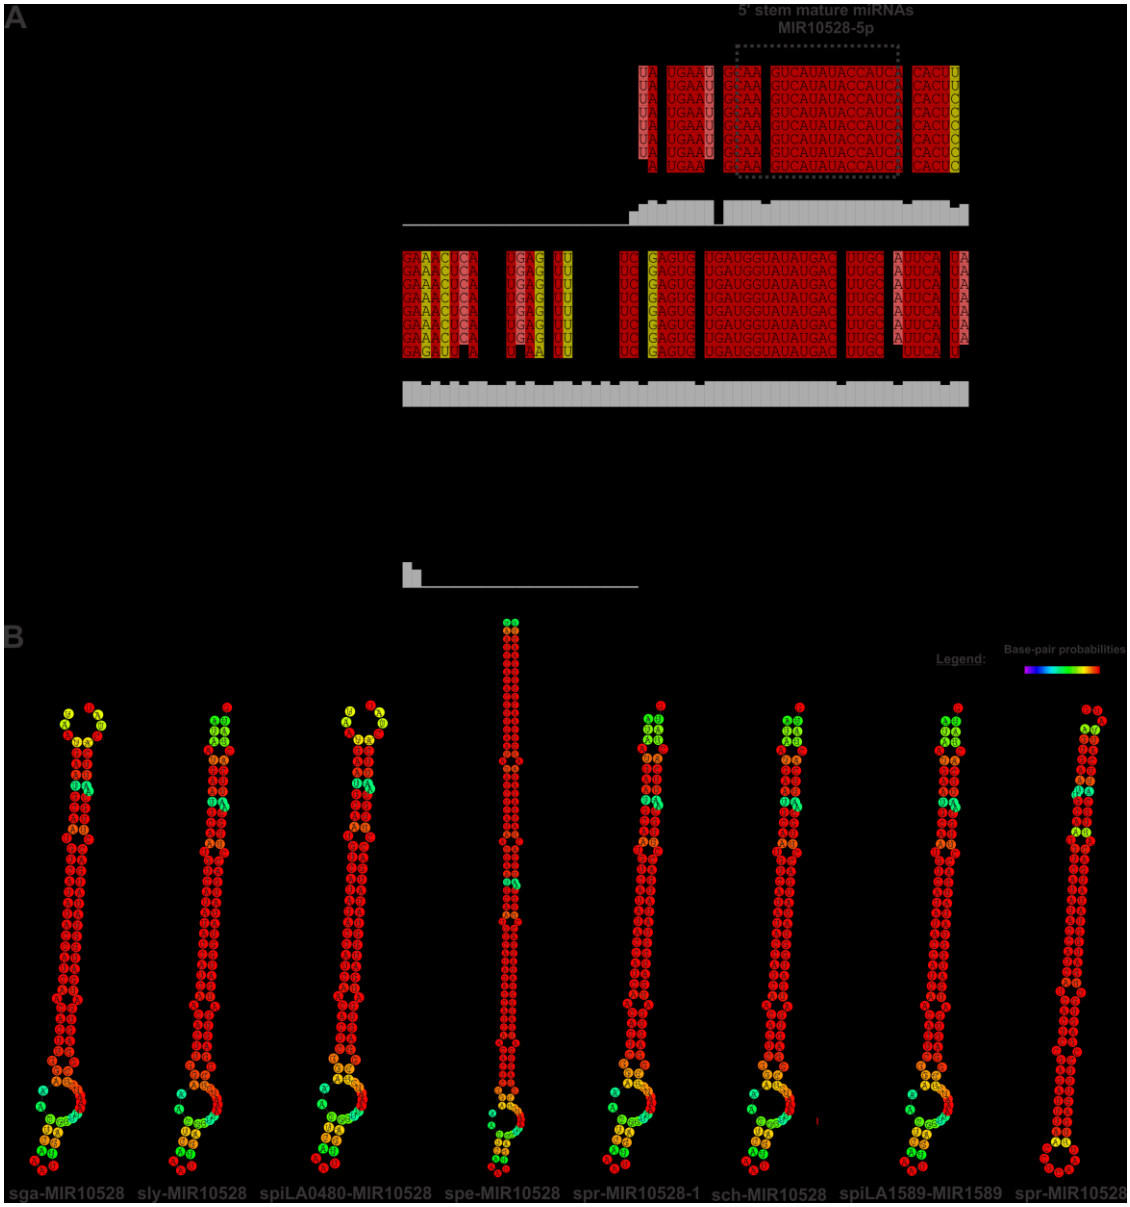

Figure 18 - (A) The high-confidence RNA alignments between MIR10528 families of *S. lycopersicum* (Sly), *S. pennellii* (Spe), *S. galapagense* (Sga), *S. chilense* (Sch), *S. peruvianum* (Spr), *S. pimpinellifolium* LA0480 (SpiLA0480) and *S. pimpinellifolium* LA1589 (SpiLA1589) were performed using RNAalifold. Mature miRNAs are shown as boxes. Brackets and colours identify matching residues in 3' stems of hairpin structures. Levels of nucleotide identity are indicated below the alignment. **(b)** Secondary structures of MIR10528 family from tomato were drawn by RNAfold.

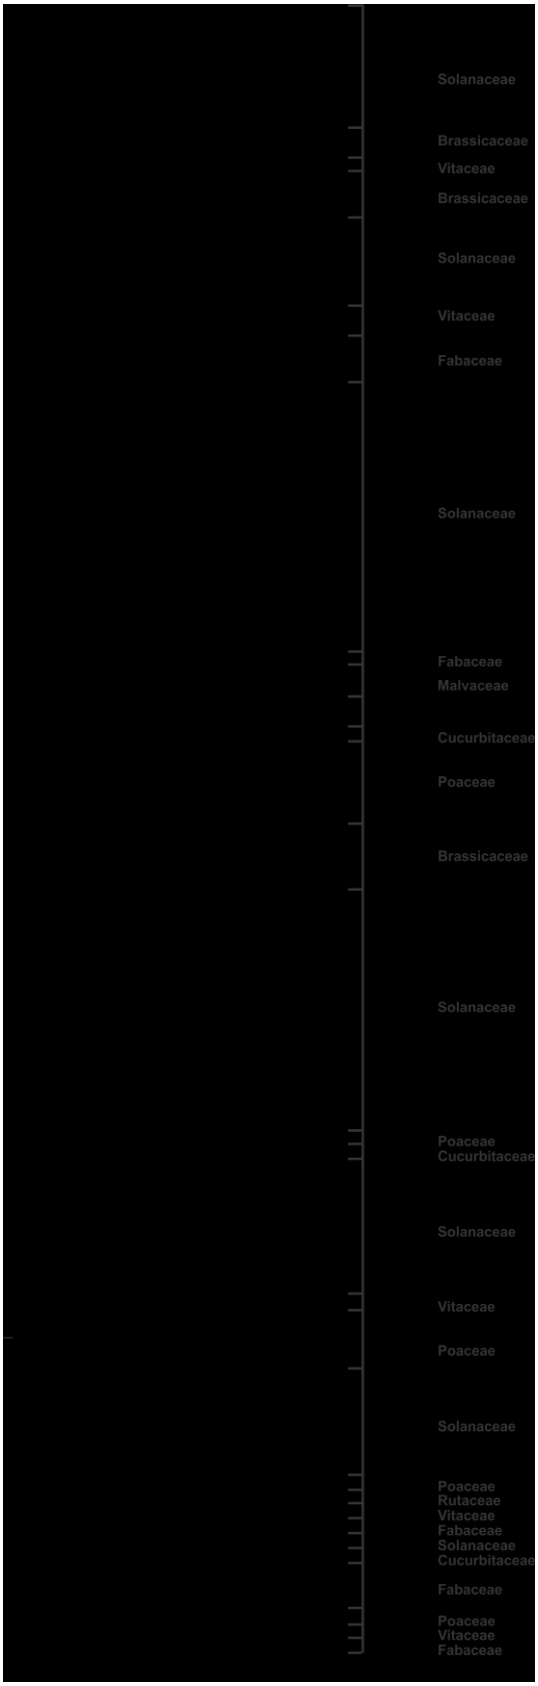

Figure 19 - Phylogenetic tree of MIR166 pre-miRNAs identified in *S. lycopersicum*, *S. pennellii, S. galapagense, S. chilense, S. peruvianum*, *S. pimpinellifolium* LA0480, *S. pimpinellifolium* LA1589 and their orthologs.

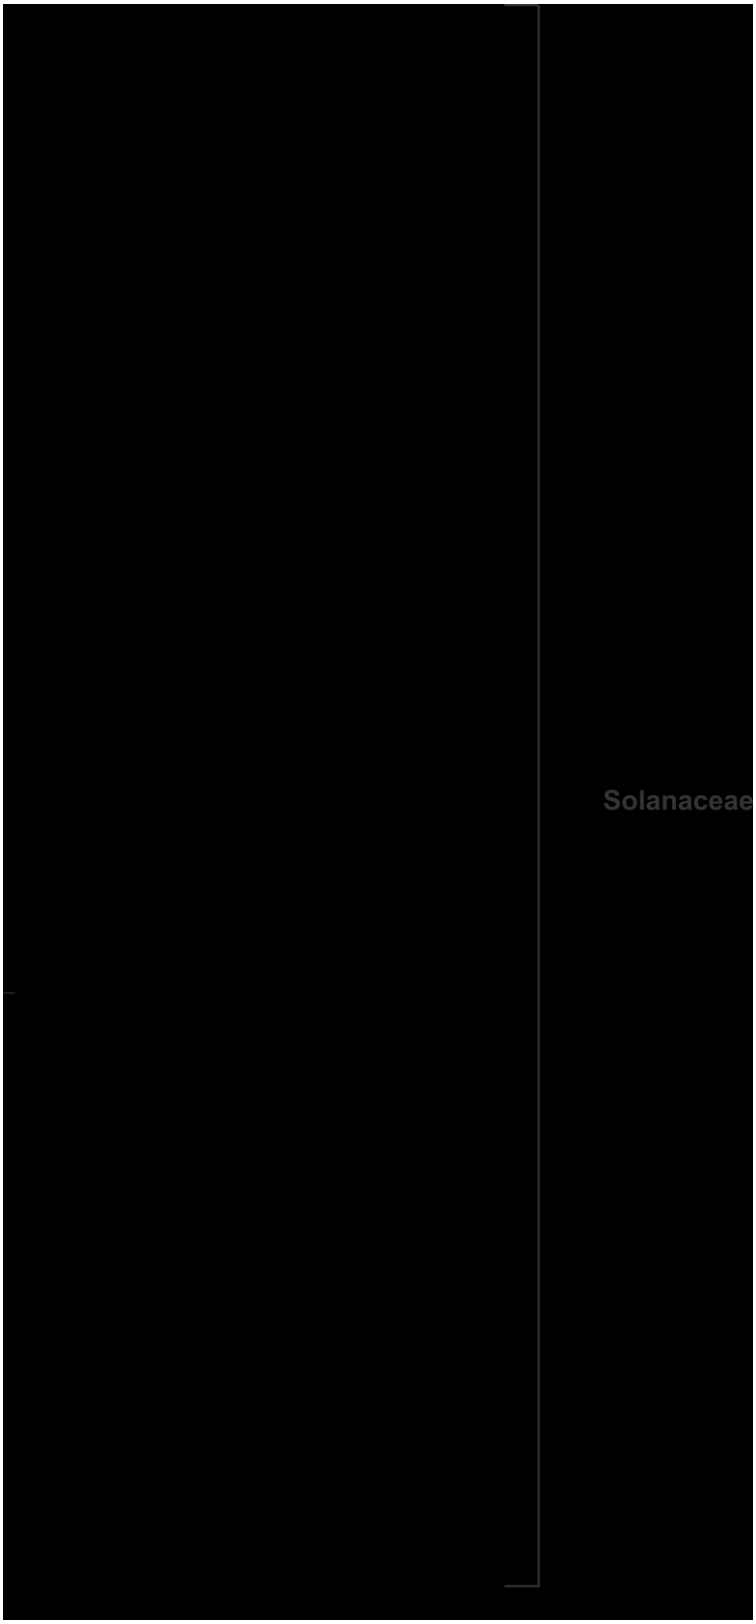

Figure 20 - Phylogenetic tree of MIR5303 pre-miRNAs identified in *S. lycopersicum*, *S. pennellii, S. galapagense, S. chilense, S. peruvianum*, *S. pimpinellifolium* LA0480, *S. pimpinellifolium* LA1589 and their orthologs.

Figure 21 - Phylogenetic tree of MIR6022 pre-miRNAs identified in *S. lycopersicum*, *S. pennellii, S. galapagense, S. chilense, S. peruvianum*, *S. pimpinellifolium* LA0480, *S. pimpinellifolium* LA1589 and their orthologs.

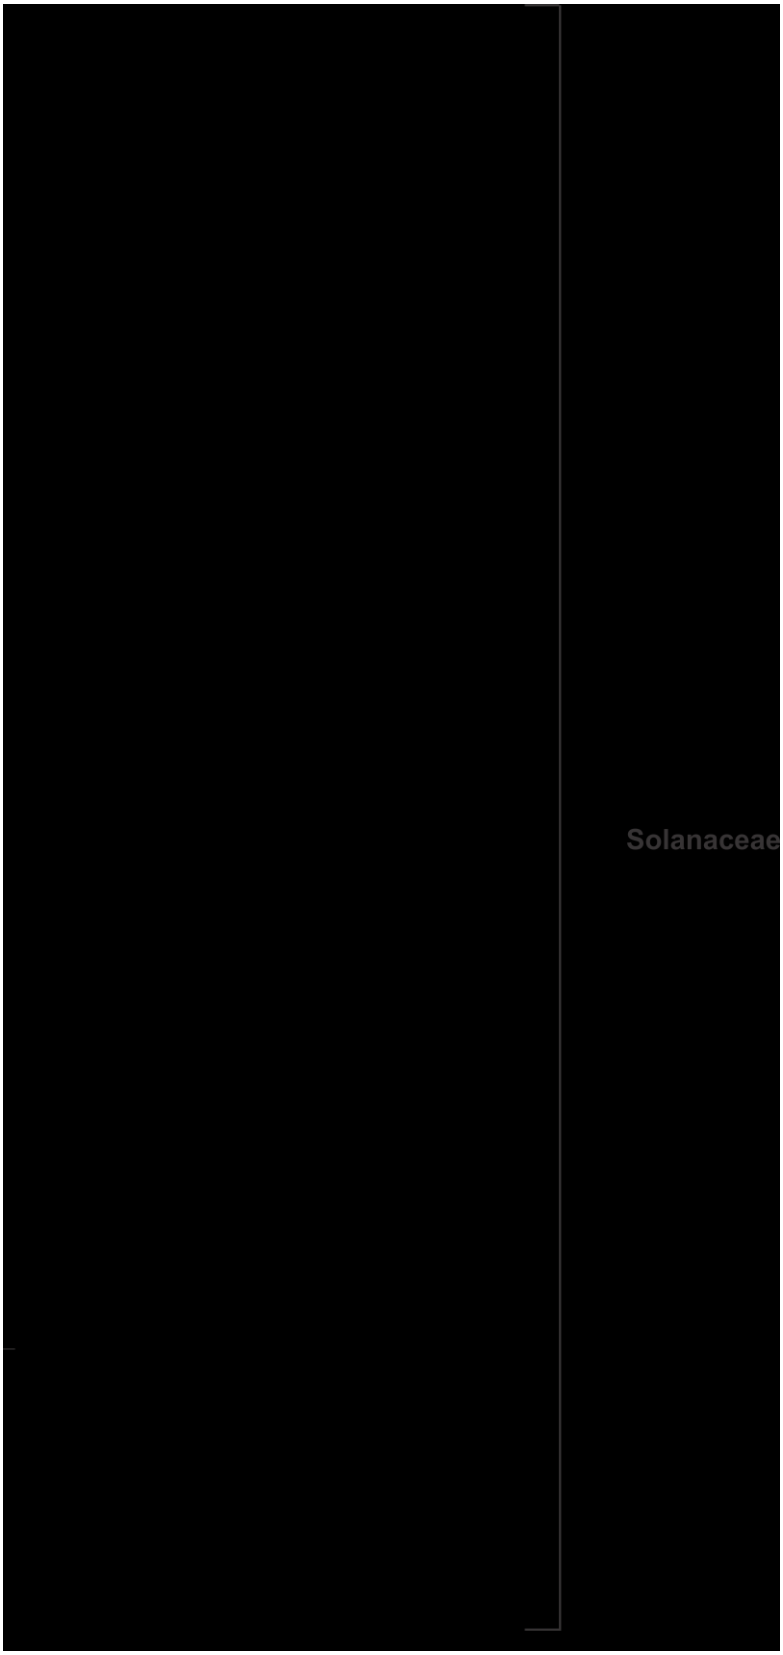

Figure 22 - Phylogenetic tree of MIR7981 pre-miRNAs identified in *S. lycopersicum*, *S. pennellii, S. galapagense, S. chilense, S. peruvianum*, *S. pimpinellifolium* LA0480, *S. pimpinellifolium* LA1589 and their orthologs.

Figure 23 - Phylogenetic tree of MIR10528 pre-miRNAs identified in *S. lycopersicum*, *S. pennellii, S. galapagense, S. chilense, S. peruvianum*, *S. pimpinellifolium* LA0480, *S. pimpinellifolium* LA1589 and their orthologs.

7 CONSIDERAÇÕES FINAIS

Considerando a importância global da cultura do tomateiro e os problemas gerados pela susceptibilidade às pragas do tomate cultivado e as diferenças com os tomates selvagens. Considerando a relevância de entender mais sobre os mecanismos de regulação gênica em *S. haematobium*. Nossos resultados expandem o estudo de miRNAs em plantas e animais ao fornecer um melhor entendimento dos papéis essenciais nos processos de regulação baseados em miRNAs em tomate e *S. haematobium*, suas vias de processamento e expressão gênica, além de fornecer alvos para investigações futuras. Além disso, estes resultados abrirão um novo caminho para o estudo dos miRNAs na biologia do esquistossomo e em tecnologias que envolvem o controle do silenciamento gênico neste organismo. Além disso, permitirá a compreensão de diversos processos e mecanismos em sua biologia, uma vez que essas moléculas apresentam importante papel regulatório para diferentes mRNAs, afetando diversas características do organismo em diferentes estágios e condições ambientais. Ainda, o entendimento do possível envolvimento dos acilaçucares na resistência aos artrópodes e sua associação com marcadores relacionados a características importantes auxiliará no melhoramento genético dessas espécies de tomate visando uma resposta ao controle do estresse biótico. Nesse sentido, tendo em vista o importante papel da produção de aleloquímicos em *Solanaceae*, nossos resultados contribuem para um melhor entendimento dos acilaçúcares e suas vias de processamento e abrem oportunidades para estudar sua relação com a resistência biótica nessas importantes espécies de vegetais e outras espécies de *Solanaceae*.

APÊNDICE III - SUPPLEMENTARY TABLES - CAPÍTULO II – Article: Genome-wide identification and characterization of genes involved in the acylsugar pathway in tomato - Manuscript Draft sob revision for Plant Gene Journal

Supplementary Table S1. Primers designed for real-time PCR from the putative genes sequences of the acylsugar pathway and reference endogenous genes.

Gene	Sense primer	Antisense primer
BCKD E2	5’ TGTTATCCACACCTGCTGTCC 3’	5’ GTATCCTTCCACCTTTCCCAG 3’
IPMSA	5’ CAACGAGGCAAATTATCTGAC 3’	5’ GTTTAGCAGTCATGGATGCAC 3’
TD	5’ AACTCCCGAAAGAGCAGTTG 3’	5’ TCGCAGCCAAGTCTCTGAG 3’
eEF-1	5’ TTGACAGGCGTTCAGGTAAGG 3’	5’ GGGCTTGGTGGGAATCATC 3’
GAPDH	5’ CTGTTGATGTGTCCGTGGTTG 3’	5’ CAGATTCCTCCTTGATGGCAG 3’

Supplementary Table S2. Proteins involved in the acylsugar pathway in *Solanum lycopersicum* (Sly) and *Solanum pennellii* (Spe) retrieved from Sol Genomics Database. Chromosome (Chr).
